It should also be apparent that as any individual's identifications are multiple and variable, recognition requires sensitivity to the identity definitions that people themselves hold in any specific scenario. It is one thing to willingly identify in terms of a particular identity; it is another to have one's choice over one's identities limited by others. Sen (2006) illustrates this with the observation that while an individual's Jewishness may be of immense personal value and political significance (e.g., in collective action against anti-Semitism) "it would be a long-run victory of Nazism if the barbarities of the 1930s eliminated forever a Jewish person's freedom and ability to invoke any identity other than his or her Jewishness" (p. 8). Moreover, individuals may experience their various social identities as mutually constitutive such that others' failing to recognize one element of one's identity may have implications for one's experience of another. Thus, if one identifies as a British Muslim, others' orientation to just one element of one's self-definition, even if it is deeply valued, may be problematic. For example, others' orientation to one's Muslim identity may limit one's ability to speak and be heard in terms of one's Britishness (Hopkins and Blackwood, 2011). So too, the misrecognition of one's Britishness may be experienced as compromising one's understanding of one's religious identity (e.g., as an identity that can accommodate to different national contexts: Hopkins, 2011).

Identity Boundaries

A social categorical definition of the self and others implies the definition of group boundaries (such that some are defined as in-group and some as out-group). These boundaries vary according to self-category salience. Thus with one social identification (e.g., a supporter of a particular football club) others – e.g., fans of a rival team – will be out-group, but with another social identification (e.g., those who love football), that same rival team's fan may be judged in terms of this more inclusive self-category (and regarded as a fellow). Moreover, such variation in the inclusivity of one's salient social identification has implications: Levine et al. (2005) show that the help extended to the same person depends on whether they are included within the situationally salient social self-categorization or not.

Moreover, the boundaries to any social identification are the products of human imagination, collective opinion, and social practice. This is well illustrated with the example of the nation where it is common to distinguish between more exclusive 'ethnic' conceptions of belonging and more inclusive 'civic' forms of belonging. In different countries different weightings are given to ethnic and civic criteria. However, even within the same nation there is variation in the degree to which particular criteria are adopted and hence different understandings of what defines the nation and who can identify with the nation (Pehrson et al., 2009). Moreover, it is possible to manipulate people's conceptualizations of the boundaries to their self-defining social categorizations with implications for the range of people who may receive the benefits of in-group membership (e.g., being listened to, receiving needed help: Wakefield et al., 2011).

As such boundary definitions are so consequential, it should come as little surprise to find that they are sites of argument and dispute, and this again emphasizes the importance of considering the social, cultural, and political factors that shape people's understandings of themselves and how they relate to others. Consider, for example, the fate of Bulgaria's Jewish population in the era of the Nazi Holocaust. Whereas Jewish communities across Europe were delivered to the Nazi's concentration camps, Bulgarian Jews were not. Rather, Bulgaria's Jews were defined as Bulgarian nationals and many non-Jewish Bulgarians were drawn to large-scale demonstrations on their behalf. This does not mean that there were no Bulgarian anti-Semites. Rather it reveals something of the extent to which the criteria for national inclusion are the products of social and political argument. Whereas the advocates of deportation depicted Bulgaria's Jews as 'community aliens,' others countered that Bulgaria's Jews were members of the national in-group, sharing Bulgarian values (Reicher et al., 2006). Such counterarguments also maintained that to collude with Nazi ideology would threaten Bulgaria's reputation and national interests. In other words, whereas the prodeportation argument depicted Jews as a threat to national identity their opponents construed collusion with the Nazis as identity-threatening. Again, in-group pride is not to be equated with discrimination and violence against minorities: it can also be mobilized in their defense. Which it will be is dependent on the social and political context and which constructions of identity gain popular support.

Representations of Identity

Social identifications are not the product of a lone individual's imagination. What it means to be a Bulgarian, a Muslim, an academic, or whatever, is a social product. For example, it might be tempting to assume that religious identities are defined by their associated texts (e.g., the Bible, Qur'an). However, such texts are always read and interpreted in specific social and economic contexts with the corollary that the meanings of such identifications are contingent upon the social milieu. Yet, even within the same context, the reading of text is contested (Hopkins and Kahani-Hopkins, 2009) with

consequences for group members' understandings of how they should behave. Thus debates about the nature of a Muslim social identification have implications for how British Muslims should relate to non-Muslims in Britain and to non-British Muslims across the globe. Indeed, it is possible to see such identity constructions as organized to promote different forms of behavior. Thus in some constructions of identity, positive engagement with the non-Muslim social order is defined as identity-appropriate, yet in others it is defined as inappropriate, and as identity-threatening.

Such debate could be assumed to reveal a lack of a common social identification. However, unless there is investment in a common identification, debate and contestation have little logic: it is because of a common identification that debate exists, has value and is worth entering into as those with different views on how the community should develop advance different definitions of collective identity. Such debates do not always result in a consensus and the potential for schism is ever-present: yet even schism and its dynamics cannot be understood without reference to the concept of a common identification (Sani and Reicher, 1998). It is also important to note the scope to such debate. Assumptions about the immutability of identity suggest contestation to be limited to topics at the margins of group identity. Yet, debates over the meaning of an identity typically include reference to cultural figures, histories, and traditions that are familiar to all. The reason is simple: invoking such figures and histories in terms that warrant the forms of behavior that one wishes to promote is a powerful means to recruit other group members to one's cause. Indeed, the wider corollary of such insights is that group members' talk about what a social identification means (e.g., the values shared by those adopting a particular social identification) should not necessarily be understood as descriptions of a contemporary social reality. Rather, they can be conceptualized as constructions that are organized to mobilize the behavior that would bring a particular way of living and social order into being. That is, people's talk of identity can be understood as having a performative and constitutive dimension, and as organized to encourage the forms of action that would realize a particular vision of how the social world should be (Reicher and Hopkins, 2001).

Such identity definitions may involve the characterization of in-group identity. However, they may also involve characterization of others' social identifications and how they impact upon one's own group. For example, in India, Hindu nationalists have defined India as essentially Hindu and depicted Muslims as an alien and threatening other (e.g., labeling Muslims as 'Babur ki sanfan' or the children of Babur, the sixteenth-century Muslim leader who conquered lands in present day northern India). Moreover, postcolonial analysts have explored how such contemporary characterizations of Muslim and Hindu identities are only possible because British orientalist 'scholars' (often colonial administrators motivated by a concern to maintain colonial power through a strategy of 'divide and rule') created histories that implied Hindus and Muslims in India are monolithic communities with continuous but separate histories. Such colonial histories provide powerful ideological resources for the contemporary promotion of particular social categorizations and the organization of collective behavior in terms of communal categories.

Representing Identity

With regards to the issue of identity, 'representation' has two meanings. One refers to the way in which people come to understand the meaning of their group membership – i.e., who 'we' are and what 'we' value. The other refers to the issue of who can represent 'our' interests and speak on 'our' behalf. However, these two meanings of the term can be intertwined: the issue of who is best placed to represent us depends on the characterization of our collective identity. The logic to the social identity tradition is that group members seek to act out and conform to the position best exemplifying their collective identity, and that they will be drawn to the person who best encapsulates in-group identity. However, as identity is not fixed but is a site of argument and dispute, we can conceptualize leadership as a site of contestation in which would-be leaders work on the characterization of both the collective and themselves to produce a sense that the latter embodies the former (Haslam et al., 2011). This implies that analyses of leadership cannot only focus on the personal attributes of the leader. Rather we should consider what binds group members to each other and how would-be leaders actively create and maintain their 'followership' through defining themselves as embodying the identity of those they seek to lead (Haslam et al., 2011). If simplistic assumptions about the nature of identity – especially those that naturalize or essentialize identity – fundamentally limit our ability to theorize the construction of this relationship, it is important to note that they have rhetorical value. Indeed, the same features that render essentialized understandings of identity analytically weak render them politically potent. They imply boundaries that are natural and qualities that are given and fixed, and such a naturalization of the socially contingent can be an important ideological resource with which would-be leaders represent (depict) the collective, and themselves as best positioned to be its representative (speaking on its behalf).

Social Change

Just as we need to theorize how social identities are produced and reproduced through a range of social practices such that the social order is maintained, so too we need to theorize social change and how social identities are involved in such change. Much research explores minority group members' beliefs about the legitimacy and stability of group hierarchies, the permeability of group boundaries, and how, in combination, such beliefs encourage strategies of individual social mobility (in which group members attempt to leave their group and enter higher status groups) or enter into collective action to raise the relative status of their group (see Wright, 2003).

Important in such work is minority group members' awareness of alternative social arrangements. Yet, if people act in terms of their collective identities, and these are (re)-produced through wider social practices (e.g., those of 'banal nationalism'), it is not at all clear how the new identity definitions necessary for the transformation of existing social relations arise (Reicher, 1996). What is needed is some sense of agency. Yet, this must avoid a voluntarism in which anything is possible and the oppressed are blamed for the limits to their

political imagination. Moreover, even if individuals can imagine alternative social arrangements, the question of how such 'cognitive alternatives' and dissident ideas can gain currency among a wider collective, and become the basis for new forms of social action, remains. Or to put it another way, how can new understandings of the social world and the new social identifications they imply become the basis for group rather than isolated individual activity?

Insight into such issues comes from research concerning crowd protests. Although many have viewed crowd behavior as irrational and uncontrolled there is much evidence that crowd behavior is socially patterned and violent behavior (if indeed it occurs) should be conceptualized as behavior in accordance with crowd members' common social identification (Reicher, 1984). Recent work on how crowd members develop this common identification highlights the issue of identity change. For example, studies of antiroad protests show that although participants may have originally defined themselves (and acted in terms of) one identity (perhaps as local community members concerned over the loss of an area of natural beauty), they may, because of heavy-handed police action, come to see themselves in terms of a larger scale group identification subscribing to a more radical critique of authority and commercial interests (Drury and Reicher, 2000). Such analyses pay particular attention to how participants' social categorical self-definitions are affected by the response of others (especially authorities such as the police). Where there is an asymmetry between, on the one hand, how crowd members see themselves and, on the other, how they are acted upon by the authorities, crowd participants may begin to entertain (and act in terms of) alternative and radicalized definitions of crowd identity (which initially may have been shunned). Moreover, to the degree that a common social identification facilitates the coordination of behavior and the realization of this 'new' social identification, participants may experience a sense of empowerment which affirms the significance and meaningfulness of that social identification (Drury and Reicher, 2005).

Away from crowds, other research also points to the importance of intergroup interaction in fostering group members' awareness of a mismatch between how they understand themselves and their qualities and how others define them. For example, Werbner (2000) offers an account of a UK Muslim women's group that through interactions with the local male leadership underwent a change in social identification. The group, comprising middle-class Punjabi women, started as a philanthropic organisation engaging in fund-raising for projects in Kashmir and Palestine. Over time, as their campaigning plans were questioned by local male community elders, the women became increasingly aware of a mismatch between their understandings of what they could do and achieve, and what local leaders envisaged for them, and this prompted an exploration of their collective identification as Muslim women. This involved reconstructing hitherto taken-for-granted customs as not genuinely 'Islamic' but 'merely' cultural practices and they took as their role model the Prophet's wife Ayesha (celebrated for her boldness and wisdom).

The creativity and imagination exhibited in these women's self-definitions highlights the limitations of lay and academic theories of identity that imply a fixed essence. Yet it remains important to contextualize these identity constructions as productions arising in the context of intergroup argument. That is, they arose to counter alternative definitions, and, in turn, they prompted further contestation, and so on. In this process, ideas and positions that had once seemed irrelevant or inappropriate became more meaningful as the women's campaign successes highlighted the mismatch between how the women saw themselves and how the traditional male leadership saw them. The women's reformulation of their identity was not immediate nor was the course it would take immediately obvious. Rather, it was contingent on the social dynamic of intergroup dispute in which the women, individually and collectively, engaged with particular discourses of Islam and gender, and so developed new appreciations of their Muslim identification that empowered them as Muslims and as women. Moreover, Werbner describes how their successful activities had unforeseen consequences of empowering them as British citizens.

Conclusion

Everyday talk of identity is problematic. Often it implies that groups have a fixed 'essence' that exists independently of their cognitive representation and the conditions of their social construction. However, this does not mean that the concept of identity is analytically irrelevant – only that certain understandings of this term are problematic – and social psychological theorizing on social identity manages to avoid many of the pitfalls associated with taking identities as givens. It alerts us to the importance of exploring people's self-categorizations and how these social categorical definitions are variable, contingent upon context and social practice. It also alerts us to how such self-defining categorizations are psychologically consequential in making group behavior possible. The inclusivity of such self-defining social categories determines who is judged as in-group and this shapes the range of others with whom one feels a sense of solidarity. In turn, this shared social categorical definition allows group members to coordinate their goals and interests, and to enact the norms and values they associate with their common social identification.

Yet, such identity-defining norms and values are themselves the product of social processes, and again our attention must turn to the social context in which such identity constructions are produced. In turn this requires attention to the contestation over identity. Precisely because social self-categorizations shape individuals' understandings of how they should act, questions relating to which categories are used, their boundaries, their contents, etc., are inevitably the focus of human social activity with important consequences for the making and remaking of the social order. Accordingly, rather than reserving the term 'identity politics' for a distinctive form of political activity, all social and political activity may be analyzed as involving (and being accomplished through) the strategic construction of collective identity (Hopkins and Kahani-Hopkins, 2009; Reicher and Hopkins, 2001). Indeed, analyzing the process of identity construction (and the collective action that such constructions make possible) must be central to the social scientific analysis of people's world-making and world-changing social practices.

Abstract

When Erik H. Erikson (for many years the central theorist of identity) wrote about identity, he described it as a kind of consolidation of self, so that when someone achieved her identity, the way she interacted with the world–his or her ability to trust, to work, and to play–was recognized externally by others in a way that was consonant with her own internal understandings. In the closing decades of the twentieth century, that simplicity has been lost. There are at least three reasons for this: the postmodern turn in anthropology and elsewhere in the social sciences; the recent focus on power and agency; and the emergence of what is called 'identity politics.' Each takes a somewhat different perspective. Nonetheless, one can say that 'identity' is no longer conceived as necessarily unitary, and no longer perceived as a match between inner experience and outer acknowledgment, but as a kind of mastery of multiple narratives of self-presentation.

'Identity' is a vexed topic in anthropology. Simply described, a person's identity is his or her psychologically salient individuality, the way he or she feels different from or similar to other people. But what that means to anthropologists has shifted over time.

At one time, anthropologists, and perhaps all social scientists, tended to think of identity as a clear and unambiguous assertion of selfhood, which directed behavior and motivated actions. Self, person, and identity were more or less interchangeable. When Erik Homburger Erikson (for many years the central theorist of identity) wrote about identity, he described it as a kind of consolidation of self, so that when someone acquired her identity, the way she interacted with the world–her ability to trust, to work, and to play–was recognized externally by others in a way that was consonant with her own internal understandings. For Erikson, then, 'identity' was something that had to be achieved, and its achievement was a developmental milestone in the human life cycle. The Eriksonian self stood facing the world as the private awareness of that person which, when mutually recognized and consciously accepted, became her identity. "Identity formation … arises from the selective repudiation and mutual assimilation of childhood identifications and their absorption into a new configuration, which, in turn, is dependent on the process by which a society (often through sub-societies) identifies the young individual, recognizing him as somebody who had to become the way he is and who, being the way he is, is taken for granted" (1963: p. 159). By definition, identity was unitary and more or less coherent.

In the closing decades of the twentieth century, that simplicity has been lost. There are at least three reasons for this: the postmodern turn in anthropology and elsewhere in the social sciences; the recent focus on power and agency; and the emergence of what is called 'identity politics.' Each suggests a somewhat different perspective. Nonetheless, one can say that 'identity' is no longer conceived as necessarily unitary, no longer perceived as a match between inner experience and outer acknowledgment, and no longer understood as a developmental achievement. But before we discuss these changes, some discussion of terms is in order.

Definitions

At least four terms are inextricably intertwined in these discussions: identity, self, agency, and person. Were the intellectual world to be sensibly organized, anthropologists would use these four words to refer to different concepts, but that is not always the case. As a result, the discussions can seem a little murky. It is helpful in this context to turn to discussions in the psychological literature that have been read by anthropologists and to use them to clarify the central concepts.

To begin with the self, more complicated psychoanalytic approaches to the self began to emerge with the psychoanalyst Heinz Kohut's work. In a famous article (1959), he pointed out that the tools of psychoanalysis are introspection and empathy, and he argued that psychological phenomena like the self thus necessarily include introspection and empathy as essential elements. The 'I-experience,' as he called it, captures the way an individual introspects; thus evidence for the self is fundamentally different from evidence for the observable body. Kohut went on to establish his own vocabulary about the 'I-experience,' the most useful phrase probably being the 'self-object,' the other person that an individual may use to soothe himself and restore inner harmony, as a mother can reassure a child that an imagined dragon is not real. His most fundamental contribution, however (at least for the present purpose), was to distinguish between the introspective nature of the self and the differently observable nature of the person.

This is the distinction that the psychoanalyst Roy Schafer later develops as the distinction between the person, as the agent who acts, and the content of the ideas they have about personhood, the person's understanding of his or her 'I.' He calls these 'self-narratives' (but often refers to them as selves). Schafer also argues that from this perspective, there is clearly more than one self, a position that some anthropologists and psychologists also now adopt (Kondo, 1990; Gergen, 1991). There may be the self who is confident, assertive, and effective and the one who is weak, embarrassed, and reactive (it is that 'second' self which the analysand will present in the analytic hour). There is the self we become when speaking French, freer, more sophisticated, we feel, than our English-speaking self (cf Kaplan, 1993). There is

the work self, the play self, the parenting self, the self in different roles, and the self under different circumstances. Schafer (1992: p. 25) quotes a male analysand speaking to his analyst: "I told my friend that whenever I catch myself exaggerating, I bombard myself with reproaches that I never tell the truth about myself, so that I end up feeling rotten inside, and even though I tell myself to cut it out, that there is more to me than that, that it is important to me to be truthful, I keep dumping on myself." There are, Schafer suggests, eight selves of five types in that remark. The types are actual self, ideal self, self as place, self as agent or subject, and self as object. The selves are analysand self, social self (talking to friend), bombarding self, derogated self, exaggerating self, conciliatory advisor self, advisory self, and the defended self with redeeming features. Schafer is perhaps being excessive (it is his exceeding self) but the point is powerful. To call all of what his analysand describes the product of a single self is to lose a good deal of helpful detail.

From this perspective, a self–or more precisely, a self-narrative or self-representation–is a cognitive schema, a bounded collection of conceptions and images that an individual uses to perceive, to categorize, and to experience his world: in short, to think with. Clearly, people are motivated by more than one simple cognitive packet. They are Americans, professionals, parents, neighbors; they are shy in some settings, assertive in others; skilled and aggressive in some games, cautious and awkward in others. Some theorists conceptualize these 'packets' in terms of roles. Mardi Horowitz et al. (1996), more complexly, write of 'role-relationships.' We establish, they argue, particular ways of relating to people that are driven by our concepts of who they are, who we are in relation to them, and how we are to act in that relationship. They see these role relationships as integrated in a sense of personal identity. Claude Steele (1988) provides evidence for that integration in an experiment in which women in Salt Lake City were called by a man posing as a pollster. While the call was ostensibly about conducting a future poll on women's issues, some women were told that it was commonly known that they were uncooperative with community projects. Some were told that it was commonly known that they were cooperative. Some were told that they were bad drivers. Two days later, a woman called them back and asked them to help with a community project. Salt Lake City is a heavily Mormon community, with a strong ethic of community cooperation. Perhaps unsurprisingly, those who were insulted as uncooperative were twice as likely to agree to help out as those who were praised, as if to clear their good names to themselves. What was more remarkable, however, is that those who were called bad drivers were also twice as helpful as those who had been praised. Steele went on to argue that people often respond to damage to one self-representation by affirming success in another. I hang back with embarrassment as a lousy athlete when friends at a beach party decide that we should all play volleyball, but I can make myself feel better by reminding myself, when I drop the ball, that I am competent in the classroom. Those of us who drop volleyballs can enhance our self-esteem by bringing a terrific homemade pie to the next seaside event.

At the same time, the term 'self' seems to imply something more than this tale of loosely integrated but shifting schemas suggests. Cultural psychologists Markus and Kitayama (1994: p. 569) argue that "the model which underlies virtually all current social science views the self as an entity that a) comprises a unique, bounded configuration of internal attributes (e.g., preferences, traits, abilities, motives, values, and rights) and b) behaves primarily as a consequence of those internal attributes." They go on to argue that in the West, for the most part, people assume that the major normative task of the self is to maintain its independence, and in other, particularly Asian, settings, the normative task becomes maintaining interdependence with others. (This proposition has been a subject of active debate in anthropology.) They use the concept of the 'self,' then, to indicate not only schemas of the 'I,' but processes of acting in the world.

The cognitive psychologist Ulric Neisser (1988) makes sense of this confusion in an article widely read by psychologically minded anthropologists. He argues that there are five kinds of self-knowledge, five ways in which we have knowledge of our 'I.' There is the ecological self, the 'I' perceived with respect to the physical environment; the interpersonal self, experienced in emotional communication, the way 'I' behave in a particular human interchange; the extended self, based on memory and anticipation, the 'I' who has done certain things in the past and will likely engage in certain routines in the future; the private self, experienced as the awareness that other people cannot see your thoughts, that (in some ways) only I can know me; and the conceptual self, the wealth of concepts that I believe comprise my self: my roles (professor, friend, dog-owner), my features (I have a liver, a nose, and a mind), and my specific traits (I am tall, short, smart, stupid, brunette, blond). It is important, Neisser argues, to distinguish between kinds of self-knowledge, because otherwise the self is full of apparent contradictions. It is physical yet mental, public yet private, directly perceived yet incorrectly imagined, universal yet culture-specific. "Although there is nothing with which we are more familiar, we are often enjoined to know ourselves better than we do" (1988: p. 35). He resolves the contradictions, however, by speaking of different 'selves.' "They differ in their origins and developmental histories, in what we know about them, in the pathologies to which they are subject, and in the manner in which they contribute to human experience" (1988: p. 35).

The major distinction here is between 'self' and 'person.' 'Self' is used to refer to the introspective experience of the 'I,' and while there are at least two dominant ways of theorizing this experience–the first, as a collection of cognitive schemas and the second, as a more complex integration of those schemas with other psychological processes–the term focuses in on a subject-centered internal experience of the subject. 'Person,' by contrast, is an other-centered term. It evokes an individual's understanding of the shared qualities of individuals like himself or herself–the common qualities of those who have selves. Most anthropological discussion of the person takes its starting point from Mauss's (1938) famous essay. Mauss pointed out that the concept of the person changed considerably over time and across space. It was only in the Roman Empire, for example, that the concept of the person came to refer to a locus of rights, which has remained the legal meaning of person in English and American law today. As Geertz (1983: p. 59) points out, the Western concept of the person is 'a rather peculiar idea within the context of world cultures.'

The distinction between 'identity' and 'agency' redescribes that internal/external opposition in more specific

terms. 'Agency' is the volitional capacity of all persons: their ability to choose, to intend, and to act. When anthropologists talk about 'agency,' they contrast it to 'structure,' by which they tend to mean the external constraints on human freedom institutionalized within a society (the kinship structure, political structure, economic structure, and so forth; see Ortner's (1996) useful discussion).

'Identity' tends to be used for a particular kind of self: the internal, subject-centered experience of unique agency. It would (or should) seem strange to say, 'his whole self is wrapped up in being an anthropologist.' That would seem to imply that even the way he located his body in a room and his memories of childhood were somehow centered on being an anthropologist. But to say, 'his whole identity is wrapped up in being an anthropologist' means that he thinks that the way he currently chooses, intends, and acts has a lot to do with the way he conceives of himself as an anthropologist and not as a chemist. The concept 'self' necessarily entails a sense of not being another person. 'Identity' indexes a much sharper, more conscious sense of difference: having a different kind of agency, making different kinds of choices. The term 'identity,' then, should be used for a subject-centered sense of personal agency. It answers the question, 'who am I?' by asking, 'what can I do in the world?' (See Holland et al., 1998 for a detailed discussion of identity and agency through a dialogic, practice theory orientation.)

Contemporary Influences

There are three dominant influences on contemporary identity theory within anthropology. First is the literary, postmodern turn in the social sciences. This has brought an emphasis on narrative and performance. Identity becomes something which individuals perform, enact, and present; often, the medium of performance is understood as narrative (see Steedly, 1993; Stewart, 1996). Lavie's *Poetics of Military Occupation* (1990) is a good, relatively early, example of this kind of work. The goal of Lavie's ethnography is to describe the way Bedouin have come to understand themselves as actors in the world. She presents this through presenting the performance of different Bedouin roles–the sheikh, the fool, the old woman–and through the stories Bedouin tell about themselves. And she uses photographs which, unlike the photographs of most ethnographies, enact the thesis of the book.

Second is the emphasis on power and agency. Like the literary, postmodern turn, this influence permeates much of contemporary anthropology. Its relevance to identity theory lies in the way agency is understood to act within the constraints of external power. Ethnographies with these concerns focus on those who would seem deprived of power or importance, and then demonstrate how even within the margins of the nation-state, or in the lowest ranks of the factory, people identify themselves as effective actors in the world. For example, Tsing (*In the Realm of the Diamond Queen*, 1993) organizes her ethnography around a woman who is not only marginal in the eyes of most Westerners (she lives in the Indonesian hills) but in the eyes of her own people: she is intermittently psychotic and is the leader of a small, unpopular cult. Tsing uses her speeches as the vehicle to illustrate how those on such margins nevertheless conceive of themselves as effective actors in relationship to the center, and to some extent actually are.

The third and most powerful influence comes from cultural studies, and more specifically from postcolonial studies and identity politics. Postcolonial studies focus on relationships between the colonizer and the colonized, and identity politics on relationships between different races and/or genders, but for both the central issue is an asymmetrical power relationship and its consequences.

Memmi's *The Colonizer and the Colonized* (1965) is a foundational text in postcolonial studies. Memmi argues that he who is colonized models himself on the colonizer, aping his customs and yearning for his appearance. He loses his past; he learns the history of Cromwell but nothing of his own progenitors. He grows embarrassed by his mother tongue. "The first ambition of the colonized is to become equal to that splendid model [of the colonizer] and to resemble him to the point of disappearing in him" (1965: p. 120). The colonized agrees, in Memmi's words, to destroy himself and become what he is not. But then he learns that in the end the colonizer will reject him anyway, and he is filled with shame and self-hatred (1965: pp. 121–122). Ultimately, he has no choice but to recognize the anger in his ambivalence and to rebel. "Revolt is the only way out of the colonial situation, and the colonizer realizes it sooner or later" (1965: p. 127). And yet even if he is successful he remains still tortured, still living in a psyche defined by the colonizer, defined by what he is not. "So goes the drama of the man who is a product and victim of colonialism. He almost never succeeds in corresponding with himself."

Frantz Fanon, in *Black Skin, White Masks* (1967), wrote even more starkly about colonialism and race: "for the black man there is only one destiny. And it is white" (1967: p. 10). The terrible cost of colonialism in Fanon's eyes is that, in yearning to be like the white colonizer, the black colonized man comes to accept the white man's degrading vision of the black man and so to lose himself. He is alienated from himself when he feels most white, and humiliated when he feels most black. And so, perpetually, the black man is torn, rejecting himself to become white, only then to grasp a more terrible vision of his never-to-be-scrubbed-clean skin. "A Negro is forever in combat with his own image" (1967: p. 194).

Identity politics takes this central relationship between a dominant group and a subordinate group, an us and a them, and makes theories out of the attempts to change it. For those confronted by the inferiority of their skin, gender, or accent, should they adopt the mainstream style and hope to be respected, or reject the mainstream in order to build a world in which its values will not matter? Those who write within this arena tend to see the route to political resolution of their problems through the conceptual deconstruction of this basic opposition. West, for example, writes of the 'double consciousness' of the rejection of the mainstream (and its association of blackness with inferiority) while assimilating into it. He writes admiringly of "cultural workers who simultaneously position themselves within (or alongside) the mainstream while clearly aligned with groups who vow to keep alive potent traditions of critique and resistance" (1990: p. 33).

Bhabha, another central voice in identity politics, similarly diagnoses the central problems of the colonized subject as ambivalence and hybridity. The colonial subject identifies with

the colonizer and yet cannot be the colonizer. If he identifies with his nativeness, he confronts his own condemnation; if he identifies with the Westernization he has adopted, he confronts his own alienation. "The taking up of any one position, within a specific discursive form in a particular historical conjecture, is then always problematic" (1990: p. 81). Bhabha uses the word 'hybridity' to describe the solution, or condition, of the multiply defined self which both reiterates binary colonial categories and ultimately subverts them, but through echoes and not direct opposition. Bhabha suggests that the post-colonial subject, the marginal subject, is someone who feels that her capacity for self-declaration has been taken from her repeatedly through a long history in which she has been forced to conform to the dominant culture's prejudices and biases.

As a result, the politics in identity politics become fragmented and complex. Another theorist, Lata Mani, argues that to understand these different perspectives as a unity "sets up problematic chains of equivalences between, say, people of color in the United States, people from the third world, lesbians, gays … It is not as though difference is not acknowledged, for an inventory of difference is crucial to this narrative; rather it is that difference is insufficiently engaged" (1992: p. 393). Political affiliation becomes possible only though acknowledging difference, because these politics are as much about selfhood as about political economy.

Bhabha sees this complexity of identifications as a condition of modernity. This does tend to be a view about elites (or the middle class) by those who are elites (and have money to spend at Tower Records) but, as elites, many theorists agree. The anthropological critic James Clifford (1988: p. 11) diagnoses contemporary identities thus: "intervening in an interconnected world, one is always, to varying degrees, 'inauthentic': caught between cultures, implicated in others. Because discourse in a global system is elaborated vis-à-vis, a sense of difference or distinctness can never be located solely in the continuity of a culture or tradition."

Contemporary Identity

One could argue that the mastery of multiple narratives is the core project of the postmodern politics of identity. This perspective on identity is quite different from Erikson's naturalistic vision of an identity which can be intuited by an objective observer over a limited period of time. The most insistent message of these identity theorists is the refusal to be characterized by someone else's narrative, and to assert their own authority in laying claim to a narrative of agency that ultimately may not be so different from those they have rejected. When Gayatri Spivak (1987), for example, denounces her characterization as a Marxist, a feminist, a deconstructionist (she is famous for being all three), she does so, one suspects, not because she rejects the personal resonance of those categories for her, but because she resists having them imposed. When members of an academic culture are complicit in the dicta that only women can write on feminism, only men may write about the men's movement, only African-Americans can write on black politics, we acknowledge the importance of allowing those who have been disempowered to experience empowerment through the casting of their narratives of self-characterization.

From this perspective on the politics of identity, successful (healthy, appropriate) identity in a modern postcolonial context is less a self-characterizing narrative with a mirroring world than a sense of command over narrative complexity: narratives which one has to some extent chosen, whose mastery gives one a sense of direction, adequacy, and goodness. Rather than locating identity in single narratives, or in narratives matched to external approval, we capture more of the emphasis of these accounts in their experience of comfort and control in slipping from one narrative to another (see Luhrmann, 1996). This comfort is what Schafer evokes in his account of the freeing of the 'imprisoned' analysand: not that the analysand is unconstrained by narrative, but that the analysand comes to feel that her narratives of personhood, complex and contradictory as they might be, are those that she has chosen–that rather than being controlled by the brute oppression of a narrative externally imposed, she is in mastery of the narratives which structure her presentations of personhood to the world.

But, as the decades pass, that formulation will change again.

This article is a revision of the previous edition article by J.E. Marcia, volume 11, pp. 7159–7163, © 2001, Elsevier Ltd.

Abstract

Identity development during childhood and adolescence is discussed from the perspective of identity's 'architect,' Erik Erikson. Historical origins of Eriksonian concepts are presented from both classic psychoanalytic as well as object relations theory. The precursors to identity in infancy and childhood are then described, the identity formation process is detailed, and its consequences in adult life are examined. Criticisms of Erikson's work are presented, followed by a review of key findings from studies exploring identity's antecedents, developmental pathways, and consequences. Current directions in identity research are presented and directions for future research are detailed in conclusion.

Identity can be defined as the entity that gives one the power to move with satisfying direction in one's life and to recognize and be recognized as a unique individual by others in the social context. Erik Erikson (1963, 1968) first used the term identity in his clinical practice to describe a psychological entity that seemed missing in the lives of some of the young men returning from World War II. These men knew who they were personally, but their lives seemed to lack a sense of coherence and continuity with what had gone before the War and what might potentially follow. Erikson described identity as a psychosocial phenomenon, rooted both within the individual and also within the social context. He saw adolescence as the time in the life span in which the establishment of an identity came to the forefront of psychological concerns. Today, there are different ways of defining identity as well as different research approaches used to explore identity's many dimensions (see Kroger, 2007, for a review of these approaches). For purposes here, the development of identity in childhood and adolescence will be examined through the psychosocial framework of Erik Erikson, for it is this approach that has generated the greatest body of theoretical work and empirical investigations. I begin with a brief comment on identity's psychoanalytic origins, as well as proposals from object relations theory that describe the development of the self in early childhood, a precursor to the identity formation process of adolescence. I continue with a more complete description of Erikson's identity concept and some of the research that it has generated, and conclude with comments on the ramifications of identity development during and beyond adolescence.

Precursors to Erikson's Concept of Identity

Classic Psychoanalysis

Freud used the term identity only once to refer to his ethnic (Jewish) origins (Erikson, 1959). However, Freud's (1937) work on the basic drives, psychic energy; the roles of the unconscious, preconscious, and conscious thoughts in personality development; the role of the defense mechanisms; and the balances among the id, ego, and superego in personality functioning served as the foundations for Erikson's thinking. Erikson's initial work as a teacher at a small school in Vienna with childhood friend Peter Blos brought Erikson into contact with Freud's inner circle. Invited by Anna Freud to undertake training in child psychoanalysis, Erikson received his psychoanalytic credentials as Hitler rose to power in Europe. As a consequence, Erikson and his family immigrated to Boston, and he became the first child psychoanalyst trained by Freud to work in the United States (Friedman, 1999). As Erikson's thinking evolved, however, he became more strongly focused on the role of the ego in development, and in how one comes to adapt to and engage with one's surrounding context. And while Freud had focused on the roles of biology and conscious and unconscious thought processes to account for personality functioning, Erikson also began to stress the role of the social context in personality development. Several of Erikson's first major works focused on the nature of identity formation from this life span perspective of psychoanalytic ego psychology (Erikson, 1958, 1968, 1969).

Object Relations Theory

Freud's work, based on biology, the drives for pleasure and aggression, and attaining drive satisfaction rose to prominence in Europe and was used by clinicians to understand human development. Soon, however, a rather different approach began to appear in the 1940s with the object relations theorists, who suggested that the motivation for relatedness should either supplement or replace Freud's emphasis on drive discharge as the impetus for human behavior. Object relations thinking is perhaps of greatest relevance for understanding later identity formation, for it details how the development of a sense of an autonomous self emerges during infancy. Object relations theory, in general, is a branch of psychodynamic thinking that focuses on how relationships with others are the basis for the development of a sense of self during life's earliest years and of how these relationships lie at the root of later adolescent and adult personality development, in general, and identity development, in particular.

In the 1960s, psychoanalyst Margaret Mahler and her collaborators began to theorize about how a sense of self develops during infancy and early childhood (Mahler et al., 1975). Working with extensive, video-taped observations of

mothers in interactions with their infants and young children in normal child care settings, Mahler and her colleagues came to propose the course by which one develops an autonomous sense of self during life's earliest years. Mahler used the terms separation and individuation to describe two developmental tracks important to this process. By separation, Mahler referred to the child's psychological emergence from an undifferentiated sense of oneness with the primary caretaker, the symbiotic union. By individuation, she referred to the child coming to assume his or her own unique and individual psychological characteristics. Normatively and ideally, these two developmental tracks occur concurrently, according to Mahler.

Mahler et al. (1975) continued to define a series of phases in what they termed the separation-individuation process of infancy. These phases represent gradual steps by which the young child comes to develop a sense of self, basic to any later sense of identity. Initially, the newborn finds differentiation of the self from its surroundings difficult through cycles of drowsiness, alert inactivity, hungry alertness, feeding, further drowsiness, and sleep. There may be relatively little awareness of where the boundary lies between external and internal worlds. From this normative autistic phase, a gradual awareness of the primary caretaker emerges at about 3–4 months, but this caretaker is perceived merely as an extension of the infant's own self. From this phase of symbiosis, the foundations are set for the beginnings of the separation-individuation process of infancy. More recent research has challenged the existence of these earliest phases, however, suggesting that important infant capabilities for self-differentiation do exist. In response, Pine (2004) has countered that infants experience periods of nondifferentiation that carry an affective significance strong enough to account for merger desires observed in later life. Pine has argued for the continued applicability of Mahler's work, albeit with a recognition of significant accomplishments during infancy and individual differences in the separation-individuation process.

The initial phase of the separation-individuation process, termed differentiation, refers to the time at which the 5- to 10-month-old infant slides from the caretaker's lap and begins to explore the external world. With increased locomotion, practicing, at about 10–15 months, follows for the toddler. This phase is marked by increased exploration and exhilarating engagement with the world, possible as long as the caretaker remains in place to serve as a base for emotional 'refueling.' By about 15–22 months, the child begins to experience his or her primary caretaker as a person in his or her own right, and the crisis of rapprochement ensues. During this time, the reality begins to dawn that one can no longer return to the symbiotic union of earlier times, and there are likely to be repeated attempts to engage the caretaker in external activities to fill what has come to feel like an internal vacuum as the separation-individuation process ensues. A second caretaker here is vital in helping to support the child against the regressive, symbiotic pull. Eventually, an optimal outcome to this crisis results in what Mahler terms object constancy, referring to the child's internalization of the primary caretaker's image that enables the child to function in the physical absence of his or her caretaker; in this way, the child can carry mother (or the primary caretaker) in his or her mind while pursuing independent activities. This intrapsychic structural arrangement will serve the child well until adolescence.

Although Mahler et al. (1975) never discussed the implications of an optimal separation-individuation process beyond childhood, Peter Blos (1967: p. 168) quickly appreciated the application of Mahler's work to understand intrapsychic restructuring during adolescence. He termed this series of developments the second individuation process: "Individuation implies that the growing person takes increasing responsibility for what he does and what he is, rather than depositing this responsibility onto the shoulders of those under whose influence and tutelage he has grown up." Blos compares Mahler's infant differentiation phase to the adolescent process of loosening ties with the internalized parent in order to develop new romantic relationships outside the family; both theorists, however, point to the importance of maintaining strong family relationships in the external world during intrapsychic restructuring. Blos (1967) also finds striking parallels between the normative infant regressive behaviors of the rapprochement crisis to the regressive behaviors of the adolescent during the second individuation process. Subsequent research linking the intrapsychic restructuring described by Mahler and Blos to Erikson's psychosocial concept of identity development will be described in a later section.

Erikson's Identity Concept

Identity was a central theme in Erikson's own life. He never knew his biological father, an issue that haunted him throughout his life (Friedman, 1999). Erikson felt a 'stepson' relationship both to his own family and to his psychoanalytic profession that he entered without ever having earned a single university degree. In response to questioning by Robert Coles (1970: p. 180) about his youth, Erikson remarked, "Yes, if ever an identity crisis was central and drawn out in somebody's life, it was so in my own." Thus, Erikson was intimately aware of identity difficulties, and this experience, along with those of the returning soldiers he saw in his clinical practice, enabled him to understand and elaborate details of identity's elements in ways that others had not previously attempted; such personal experiences also, no doubt, sensitized Erikson to questions about identity's origins and development in the broader, nonclinical population.

Erikson (1963, 1968, 1969) defined identity in different ways over the course of his extensive writings on the topic. Above all, identity, in Erikson's view, is a psychosocial phenomenon, determined in part by one's biology, but also by one's own conscious and unconscious desires, one's psychological needs and wishes in interaction with the demands and responses of one's social environment. Identity gives one's life a feeling of sameness and continuity, despite the different roles one may assume and the different contexts in which one may operate. Identity has its roots in childhood and consequences in adulthood. According to Erikson, identity is an evolving configuration or structure, resulting from successive ego syntheses and resyntheses over the life span.

Erikson described the psychological process of introjection in infancy and identification in childhood as necessary foundations for the identity formation process of adolescence. During infancy, the young child 'takes in' (internalizes) or incorporates the images of significant others from, ideally, satisfying relationships, and these introjects, in turn, serve as the foundation for the development of a sense of self. In childhood, through the process of identification, the child assumes valued traits and characteristics of important others, in wanting to be like them. Erikson (1968) notes, however, that identity formation can only begin when the process of identification ends. Through the identity formation process, the adolescent begins evaluate the fit between previous identifications and his or her own truly unique abilities, interests, wishes, and talents, in efforts to find meaningful forms for their expression within the social context. Erikson noted that identity is not merely the sum of previous identifications, but rather a new structural configuration resulting from syntheses or repudiations of these earlier ways of being. In Erikson's (1968: p. 158) terms, identity is "a new, unique Gestalt which is more than the sum of its parts."

The formation of identity, in Erikson's view, is based on resolutions to a series of hierarchically organized psychosocial tasks met in previous life stages, and identity resolutions, in turn, determine the ways in which life tasks of adulthood can be met. Through his epigenetic principal, Erikson believed that failure to resolve, optimally, earlier life tasks would invariably result in more limited possibilities for the resolution of subsequent life tasks. Finding an optimal balance to the infant's task of Trust versus Mistrust lies at the heart of optimal identity development as well as personality development more generally across the life span; optimal work with this task provides an outlook of hope for the ensuing psychosocial tasks of life. The toddler's resolution to life's second task of Autonomy versus Doubt and Shame optimally provides the toddler with a sense of will, vital to one's later identity development, while the young child's confrontation with the task of Initiative versus Doubt and Shame ideally results in a sense of purpose. The school-age child's optimal resolution to Industry versus Inferiority instills a sense of confidence, vital to the task of Identity versus Role Confusion met normatively during adolescence. Thus, with more or less optimal experiences of hope, will, purpose, and competence, the adolescent is ready to begin exploring and eventually actualizing identity-defining roles and values within his or her social surrounds.

Resolutions to Identity versus Role Confusion also impact resolutions to the successive adult tasks of Intimacy versus Isolation, Generativity versus Stagnation, and Integrity versus Despair. Erikson (1968) was of the opinion that issues of identity must be fairly well resolved in order to experience true psychosocial intimacy. By intimacy, he referred to a counterpointing of identities; where one's identity is uncertain, Erikson found that one might engage in highly stereotyped relationships and/or develop a sense of deep isolation. With a strong sense of identity in place, the ability to love is the optimal outcome of Intimacy versus Isolation in late adolescence or early adulthood. Generativity versus Stagnation is the key psychosocial task of young and middle adulthood, involving the capacity to care for and guide the next generation, to care for one's creative products, and one's broader community. Optimal resolution to this task, possible only with optimal resolutions to Identity versus Role Confusion as well as all preceding stages, results in the ability to genuinely care both about oneself as well as others. During late adulthood, one's main psychosocial task turns to the issue of Integrity versus Despair. As the adolescent struggles to find meaningful identity directions for the future, so the later life adult must come to terms with the meaning of his or her life as is, and "the acceptance of one's one and only life cycle …" (Erikson, 1968: p. 139). Coming to terms with one's own death is a further dimension of this task. Many identity issues again arise in late adulthood, as work and parenting demands diminish and one must redefine one's way of being in the world. Optimal resolution to this final task is that of wisdom. Thus, the establishment of one's identity opens the possibilities for the capacity to love in intimate relationships, to care about the self and others, and to develop wisdom from one's life experiences in adulthood.

Erikson (1968) stresses the importance of exploration of alternatives through a moratorium process of adolescence. He has identified the areas of vocation, ideology, and sexuality to be those identity-defining roles and values generally most expressive of one's identity over the course of adolescent and adult life, at least in many Western contexts, and he stresses the dangers of early foreclosure if opportunities are not provided within one's milieu to enable identity exploration. Erikson (1968) used the term identity crisis to describe the search for a meaningful identity-defining life direction; by this term, he referred to an important developmental phenomenon, critical for optimal identity development. Should this task prove too difficult or overwhelming, Erikson described the possibilities of identity diffusion and negative identity formation as ways of avoiding or bypassing, respectively, the identity formation process. Identity diffusion is the inability to find meaningful life directions and may result in a range of difficulties from a carefree but directionless approach to life to severe psychopathology. Through a negative identity resolution, an adolescent (or adult) will adopt those roles and values that reflect a polar contrast to all those held dear by significant others. Erikson (1968) cites the daughter of an influential southern Negro minister of religion who runs away from home to live among drug addicts in Chicago.

Criticisms of Erikson's concept of identity have come from several directions. Some have taken issue with imprecise or unclear definitions of identity that Erikson has presented. At times, identity is described in structural terms, while at other times it seems to refer to a process; sometimes it is described in phenomenological terms while at others, an unconscious experience. Erikson has rather candidly stated in an interview with Stevens (1983: p. 112): "I think one could be more precise than I am or than I am able to be. I very much feel that scientific training and logic would have helped a lot." Others have sharply criticized his views as androcentric, particularly his comments on how women's identity development is based on the man (or men) she allows into the 'inner space,' as well the ordering of Identity versus Role Confusion and Intimacy versus Isolation in Erikson's epigenetic scheme (e.g., Franz and White, 1985;

Gilligan, 1982). Still others have questioned the cultural universality of Erikson's epigenetic scheme (Arnett, in press). Despite these criticisms, Erikson's (1963, 1968) identity definitions and concepts have been popular themes that researchers have attempted to examine during childhood, adolescence, and the adulthood years.

Empirical Studies of the Identity Formation Process

Erikson's (1963, 1968) writings on identity have generated much research in the social sciences over the past five decades. One general stream of studies from the 1960s through 1980s focused on the role that 'Identity versus Role Confusion' plays in Erikson's eight-stage epigenetic scheme. A further stream of work has focused on the 'Identity versus Role confusion' task in relation to other variables (e.g., Berman, 2009 on identity distress and problem behaviors), while a third approach addresses other dimensions of identity that Erikson describes in his writings (e.g., Van Hoof and Raaijmakers, 2003; on structural integration). For purposes here, it is perhaps the expansions that James Marcia (1966, 1967; Marcia et al., 1993) made to Erikson's model of identity development that have generated the greatest volume of research over the past decades.

Rather than conceptualizing the task of Identity versus Role Confusion in terms of a continuum, with identity being an entity that one has 'more or less of,' Marcia instead proposed qualitatively different pathways by which late adolescents approach the identity formation task. Marcia (1966, 1967) used the variables of exploration and commitment that Erikson had viewed as central to identity development in adolescence to propose two ways by which one might establish identity-defining commitments, and two ways by which one might not do so. Selecting the domains of vocation, ideology, and later sexual roles and values that Erikson (1968) had described as the primary identity concerns of adolescence, Marcia developed the Identity Status Interview to identify which identity approach (or identity status) was most descriptive of the adolescent's way of approach in identity-defining decisions.

The identity-achieved individual has gone through a time of exploration, based on careful consideration of his or her own interests, talents, capacities, and values to form identity-defining commitments that set one's directions in early adult life. Like the identity achieved, the foreclosed individual has equally strong identity commitments, but they have been attained without identity exploration. Most commonly, late adolescent foreclosures will merely assume the values of significant others around them and adopt a type of conferred identity. Moratorium and diffuse individuals both lack firm identity commitments, but the moratorium is in the process of trying to find personally meaningful identity-defining directions, while the diffusion is not. There may have previously been a little identity exploration for the identity diffusion, or none at all. The identity diffuse individual may be unable to adopt meaningful identity commitments for a variety of reasons, ranging from severe psychopathology to a carefree, uninvolved approach to life, just 'going where the wind blows.'

Personality Characteristics

A number of personality characteristics have been associated with those in the various identity statuses (see Kroger and Marcia, 2011, for a review). The identity-achieved individuals have demonstrated resistance to experimental attempts to raise or lower their self-esteem, and they think effectively under stressful conditions. They also demonstrate high levels of ego development and moral reasoning, are not authoritarian in their values, and use an internal locus of control in decision-making. Moratoriums share many of these characteristics with the identity achieved, although that they may be more prone to using an external locus of control than the identity achieved. In addition, they have generally high levels of anxiety relative to the other identity statuses. Foreclosures have demonstrated very high levels of authoritarian values, and they use an external locus of control. They also have very low levels of anxiety relative to the other identity statuses. At the same time, they have shown rather high levels of self-esteem. The diffusions have generally scored high on external locus of control measures and low on measures of self-esteem, moral reasoning, and ego development.

Familial Antecedents

Much research has focused on antecedents to identity development, including different resolutions to the second separation-individuation process, styles of attachment, and styles of family communication. Relatively predictable relationships between the identity statuses and dimensions of the adolescent separation-individuation process have appeared, with the foreclosure status strongly linked to an enmeshed intrapsychic relationship to the internalized parent, while the moratorium and achievement statuses have not shown this high nurturance seeking need (Kroger, 1995). A recent meta-analysis of the relationship between attachment styles and the identity statuses found weak to moderate correlations between attachment styles and the identity statuses, as predicted patterns in the relationships appeared. Secure attachment was far higher among the identity achieved compared to foreclosures and diffusions (Årseth et al., 2009). Many studies have examined family styles of communication in relation identity exploration and commitment variables as well as to the identity statuses themselves. Observational investigations of adolescents and their parents have shown adolescent identity exploration to be positively linked with family communication processes of encouragement for self-assertion, appreciation of separateness, permeability, and mutuality (Grotevant and Cooper, 1985). More recently, positive parenting during late adolescence has been linked with identity achievement and a more positive narrative resolution for a difficult life experience (Dumas et al., 2009). Additionally, achievement and moratorium identity statuses have been positively linked with clearer appropriation of parental voice in adolescent narratives (Mackey et al., 2001). Optimal identity development in adolescence thus points to resolution of the second separation-individuation process, a secure style of attachment, and authoritative communication styles used by parents.

Developmental Patterns of Change

Identity development certainly occurs over the course of adolescent and adult life, and one might question the likelihood of different patterns of change and stability over time. Waterman (1999) has proposed a series of hypotheses central to an understanding of identity status change processes, and a number of Waterman's hypotheses have recently been tested through techniques of meta-analysis (Kroger et al., 2010). Waterman suggested that identity development from adolescence to adulthood involves a preponderance of progressive identity status changes (i.e., diffusion to foreclosure, moratorium, or achievement; foreclosure to moratorium or achievement; and moratorium to achievement). Indeed, meta-analysis of longitudinal identity status investigations conducted between 1966 and 2005 revealed that a mean proportion of 36% of identity status changes would be progressive in nature. Surprising was the mean proportion of 49% for stability in identity status over approximately 3 years during late adolescence.

Waterman (1999) also proposed that over time the moratorium status would be the least stable; results of meta-analyses showed that it was, although the diffusion status was almost equally unstable. From cross-sectional studies, Kroger et al. (2010) also predicted from Waterman's (1999) hypotheses that there would be a decrease in the mean proportion of diffuse and foreclosed individuals and a concomitant increase in the moratorium and achievement identity statuses from mid to late adolescence; however, from late adolescence to young adulthood, we also anticipated an initial drop in achievement and moratorium statuses as youths entered college or adult work roles, with a subsequent increase in these statuses over time. Meta-analyses found general evidence of these patterns. Perhaps of greatest interest was the fact that only about 50% of samples were rated as moratorium or identity achieved in the 23- to 29-year age-group and only 68% were moratorium or achieved in the 30- to 36-year age span. It appears that by young adulthood, many have not established a sense of their own identity – a task that Erikson considers fundamental to adolescence.

Epigenetic Consequences

Identity resolutions have consequences for the remaining Eriksonian stages of adult life: Intimacy versus Isolation, Generativity versus Stagnation, and Integrity verses Despair. Research to date has primarily focused on the relationship between identity and intimacy. A further meta-analytic study by Årseth et al. (2009) examines the relationship between identity and intimacy during young adulthood, statistically combining results from previous studies of this relationship. Erikson's epigenetic theory was generally supported for men. High identity status (moratorium and achievement) was positively associated with high intimacy status (intimate and preintimate), and low identity status (foreclosure and diffusion) was also associated with low intimacy status (pseudo-intimate, stereotypic, and isolate). However, the findings for women were more complicated. Approximately 65% of women who were high in identity status were also high in intimacy status. At the same time, however, women who were low in identity status were almost equally distributed between high and low intimacy status groups. Furthermore, the relationship between identity and intimacy status was much stronger for men than women ($p < 0.001$). For scale measures of intimacy, high identity status participants scored higher on measures of intimacy than low identity groups, with small to moderate effect sizes whether the sample was examined in total, for men only, or for women only. In general, it appears that a foreclosed or diffuse identity resolution during late adolescence restricts the type of intimacy development that is possible during early adult life for men and at least some women. Differing contextual opportunities for the two genders may serve as a moderator for the relationship between identity and intimacy and further research is needed on this issue.

While research on identity and generativity status has been more limited, there now have been investigations supporting Erikson's epigenetic principle on the relationship between identity and integrity status during late adulthood. Perhaps the most recent and comprehensive investigation is that by Hearn et al. (2012). Hearn and his colleagues examined the identity statuses in relation to integrity statuses through the newly developed Self-Examination Interview. Results showed that some 86% of late life adults who were integrated were also identity achieved, while no despairing individuals were identity achieved. Those who were nonexploring (had not examined questions of personal meaning), pseudo-integrated (fit the world into simplistic frames and clichéd meanings), and despairing in integrity status were primarily foreclosed in identity status. Thus, those experiencing nonoptimal resolutions to *Identity versus Role Confusion* appear limited in their resolutions to *Integrity versus Despair* in late adulthood.

Summary and Directions for Future Research

Identity, with its many dimensions, has been an important entity for theory and research in the social sciences since Erikson (1959, 1963, 1968) first began using the concept in his early career. Identity, to Erikson, was a psychosocial construct that focused on the roles of individual biology, psychological processes, as well as the social context in order to account for personality development across the life span. Erikson's fifth task of adolescence, Identity versus Role Confusion, has been the focus of much theory and research over the past five decades. James Marcia (1966, 1967; Marcia et al., 1993) has been instrumental in expanding Erikson's model to describe and trace antecedents, developmental pathways, and epigenetic consequences of his four identity statuses.

Current work with the identity status paradigm has taken a number of new directions. Efforts have been made to further refine some of the statuses. Luyckx et al. (2013) have been able to validate empirically several types of identity diffusion: a 'classical' or troubled diffusion trajectory and a carefree diffusion trajectory. Earlier, Kroger (1995) was able to differentiate a 'firm' (unlikely to change) and 'developmental' foreclosure pathway with measures of adolescent separation-individuation. Luyckx et al. (2008) also have identified

several types of moratorium positions: ruminative (or maladaptive) identity exploration and two forms of reflective (adaptive) identity exploration. Preliminary work is also underway to examine possibly different forms of the identity achievement status as it undergoes change through the years of adult development. Future identity work could fruitfully undertake long-term cohort sequential studies of identity status change and stability with data assessment at relatively frequent time intervals (1–5 years). Future investigations could also usefully examine the relationship between resolutions to identity and their relations to different intimacy, generativity, and integrity statuses in adult life. Narrative strategies might usefully be employed to detail nuances of person–context interactions that are the foundation of identity development across the life span. The field of identity development throughout childhood, adolescence, and adulthood remains a rich avenue for further explorations of and refinements to Erikson's identity concepts.

Identity Movements

Abstract

The specificity of contemporary social movements is a displacement of protest from the economic and the political spheres to the cultural realm. New forms of conflicts imply identity claims and express protest against social control on different aspects of personal life. Social movements combine three kinds of claims: program, identity, and standing. The study of emotion and passion is central in identity movements. Five types of identity movements are identified: national, religious, aboriginal, particularistic, and normative. The Internet has become a key mobilizing resource for identity movements, which raise the issue of universalism versus particularism.

The main objective of social movements is to transform society so as to reflect the social actors' interests and view of the world. Such was the case with the labor movement in the early twentieth century and the decolonization movement in the 1960s (*see* Oberschall, 1983; Chazel, 1992; Buechler and Cylke, 1997). One of the characteristics of contemporary social movements is a displacement of protest from the economic and political spheres to the cultural realm. The identity movements that came to the fore in the last third of the twentieth century are of a different nature, because they express two complementary types of collective demands: (1) the defense of interests and the promotion of the rights of certain groups of individuals who feel discriminated against, and (2) the search for symbolic recognition by a significant other (a good example are aboriginal social movements). These new social movements emerged as non-class based and express a displacement to cultural issues, and to an inclusion of emotions and cognition in collective action.Movements, Social.

New forms of conflicts imply identity claims and express protest against social control on different aspects of personal life. Identity movements defend the interests, world visions, and values of groups of individuals or communities defined by such characteristics as race and ethnicity; sex; language; sexual orientation; mythical origins and ancestral territory, in the case of First Nations in the Americas and the South Pacific; and religion, in the case of certain societies, especially Islamist ones. Melucci (1996) even posits that all social movements have an identity dimension.

Identity movements have four main and very distinct objectives, some of them being more salient than others. First, they denounce injustice toward minorities. Second, they convey the idea that specific cultures must be taken into consideration when public policies are elaborated so that they meet the specific needs of minorities. Third, they demand greater control of their institutions – a demand that sometimes goes as far as self-government. Fourth, identity movements bring back particularistic values in the public and secular spheres, often opposed to by activists and characterized as 'the Western world.' This objective emerged with more salience in the 2000s.

Individuals involved in identity movements promote their own interests (Olson, 1965), but their action is also based on their way of seeing things and their personal knowledge and values. Collective action is therefore marked by instrumental (pursuit of personal interest), cognitive (knowledge), and axiological (values) rationales. Aboriginal movements are promoting a specific link with nature and are often based on the knowledge that the economic situation of the First Nations is problematic.

Boudon and Bourricaud (1982) have shown that the two dimensions of collective behavior described by Smelser (1962), relations with norms and relations with values, are so closely linked as to become interdependent. The shared values of the members of a group or community play a central role in emerging identity movements, at least as important as the pursuit of individual interests. Social movements are concerned with agency but collective action always takes place in context and structure, especially in urban environments. Contemporary perspectives on social movements does not favor either agency or social structure at the expense of the other. This is particularly true for identity movements.

This article will specify what should be understood by identity, define the characteristics of different types of identity movements, and discuss the relationship between universal and particularistic norms that are specific to each movement.

Identity

In the early twentieth century, identity was often defined according to 'objective' traits, such as English tenacity, German discipline, and French ingenuity. What we call identity was then known as the 'soul of peoples' (see Siegfried, 1950). The problem of identity is no longer seen in this light (*see* Social Identity in Social Psychology).

It is no longer possible to separate personal and collective identities. Individuals now belong to several social networks and groups, which, in turn, shape their identity, and they draw from society the elements that they need for self-definition. They are faced with a great number of choices, many more than those of preceding generations. Education, individual and collective fulfillment, social mobility, career mobility, geographical mobility, and life style are some of the social processes that help to build identity. Immigration, urbanization, international trade, unequal regional development, differing interpretations of the past, social conflicts, and

social stratification also affect the construction of collective identities (Staggenborg, 2008).

Taylor (1989) defines the concept of identity in three ways. First, identity defines the moral outlook of each individual, in the sense that individuals are able to determine what is important to them. Individual identity implies self-knowledge and a successful and accepted synthesis of diverse influences, especially those of the individual's family.

The second definition came into being with modernity and has enabled individuals to have a better grip on their own destiny. Theoretically, within the limits of their capacities, people can become what they want to be; the future is no longer dictated by ascribed status in society. Political freedom, education, and economic development have enabled individuals to innovate, and, to a certain point, be responsible for their future. Each individual may have diverging or even conflicting interests, but each will eventually define values that could eventually be expressed through various social movements and collective conduct. Taylor insists that self-affirmation and recognition by a significant other are the two conditions for achieving a successful identity. Social actors involved in identity movements are motivated by what they see as a deficiency in democracy, and by the search for recognition, which involves negotiation and sometimes struggle and which is probably the main feature of such movements (see Hobson, 2003).

Because individuals are also part of a people or nation and therefore also define themselves by their collective past, national identity is the third definition that Taylor gives to the concept of identity. A nation or historical community offers people another perspective made up of a shared culture, life style, and language; nations are also imagined communities (Anderson, 1991). However, most countries are not homogeneous and they have had to deal with the problem of recognition of various nations and minorities of all kind (especially, religious) within their own midst. One can therefore say that the relationship with the other, which is at the heart of identity assertion, is an internal problem in most countries. Dumont (1984) describes the repeated mechanisms that contribute to the building of identities: ideologies, literature, historiography, and media play a key role in the shaping of a common reference. He speaks of conflicting interpretations between various categories of actors involved in the process of building identities, and defines society as a series of interpretive practices.

The Scottish example is relevant here. Language is not a central issue in defining Scottish national identity, despite an interest in Gaelic; more important is the identification with a mythic territory, a common history, and recollection of ancestral wars (Macdonald, 1997). The situation is quite different in Quebec and Catalonia, where promotion of the national language (French and Catalan, respectively) plays a central role in the building of the respective identities.

Identity Movements

For Tilly (2004), social movements combine three kinds of claims: program, identity, and standing. "Identity claims consist of assertions that 'we' – the claimants – constitute a unified force to be reckoned with" (p. 151). There are many identity-related issues in social movements. Five types of identity movements will be characterized by the 'good reasons' (see Boudon, 1999) that inspire their action, the means and field in which the action takes place, and the meaningful others involved in the search for recognition. These types include also different motivational factors, including expectancy of success, and different processes of framing and of collective identification (Pinard, 2011). The study of aspirations, emotions, and passion became central in the analyses of identity movements in the 2000s after having been neglected by the structural and organizational models (Larana et al., 1994; Stryker et al., 2000; Goodwin et al., 2001; Fiffieule et al., 2010).

National Identity Movements

Movements of national affirmation are undoubtedly the best known types of identity movements. Gellner (1997) estimates that there are 15 000 national cultures demanding recognition in a world where there are only a few hundred nation-states. These movements challenge the dominant national reference in their respective countries, and they are determined to achieve official recognition. They are composed of national minorities – not to be confused with ethnic minorities resulting from immigration, who make demands of another nature.

National minorities fight social inequalities of which they see themselves as victims, and many demand that official institutions be modified. These types of protests generally give way to a search for a new constitutional framework within a nation-state. Situations and demands, in accordance with the historical and national contexts, are extremely diversified (Calhoun, 1996). Some identity movements transformed themselves into nationalistic movements and gave rise to political parties fighting for an independent state, as this is the case in Catalona, Québec, or Scotland.

Religious Identity Movements

Identity movements contributed to bring back religion and cultural values in the secular world described by E. Durkheim and M. Weber, especially in the public sphere as defined by J. Habermas. In that perspective, the Islamist veil is an important religious symbol and also a secular claim to recognition of a national and cultural community (see McDonald, 2006, for a discussion of this issue).

Aboriginal Identity Movements

The self-assertion of aboriginal nations in countries shaped by influxes of immigrants must be considered separately. There are approximately 300 million aboriginals living in these immigrant societies throughout the world, mainly in the Americas and the South Pacific. This enormous population is divided into several thousand nations or distinct groups. In Canada, for example, there are 633 different bands and aboriginal nations – some groups numbering only a few hundred people – speaking 57 different languages.

Conquest and colonization by Europeans marginalized aboriginal nations, sometimes moving them to reservations, as is still the case in Canada and the United States. They are

demanding control of a number of institutions that will help them maintain their specific collective identities. Some aboriginal nations are striving for self-government within their respective countries, but their small populations prevent most of them from claiming complete sovereignty.

Aboriginal communities build their action on three main aspects of their value system. First, there is the feeling of a common mythical origin. Second, and probably at the heart of their culture, is their relationship with nature, the land, and ancestral territory. Third is the idea of kinship and blood; aboriginal communities generally do not integrate strangers, for one is either born Native or one is not.

The search for symbolic recognition is particularly important to aboriginal communities, since their culture has been denigrated. The leaders of these communities are striving to build a new sense of identity in order to counteract the feeling of self-contempt. This explains why, for many of them, interpretation and self-definition have become so important (Nagel, 1995). Aboriginal movements illustrate the institutionalization process of social movements when elite and professionals take in charge the claims and negotiate with governments.

Particularistic Identity Movements

Other identity movements do not question existing institutions but aim for the rightful participation of specific groups of individuals, sometimes even imposing various modes of participation suited to their particular characteristics. Such is the case with linguistic or ethnic minorities that insist on having better access to important positions in the civil service and business organizations (Jasper, 1997).

This type of movement includes the great majority of the feminist movements that demand an end to sex discrimination in public institutions and private enterprises. Although the feminist movement has very diverse components, it presents itself as an identity movement because it defends the interests of a portion of the population who feel wronged because they are women, and because of their opposition to a significant other who, in turn, becomes the main point of reference: men. Groups of women now insist on empowerment and their share of all higher appointments in various occupations. The most radical feminist movements go so far as to claim that all social relations are 'gender relations.'

The civil-rights movement for black Americans, which climaxed under the leadership of Martin Luther King, is also an identity movement (Morris, 1984). Even though this movement is typically American, in the second half of the twentieth century, it has taken on a very important symbolic value in most Western countries; it also gave rise to programs of affirmative action in favor of visible minorities in the United Sates.

Normative Identity Movements

Other identity movements set out to modify social norms that affect private, civil, and professional lives of individuals, as old social movements succeeded to do so (working hours, for example). Actors in these movements aim for symbolic acceptance of their differences and want to change social stereotypes. These differences are of a sexual, intellectual, or physical nature, such as the visible characteristics of certain immigrants (Baumann, 1996). Movements based on sexual orientation and in defense of the handicapped are good examples of this type of group, whose members feel that they are the victims of prejudice (Taylor and Whittier, 1997). Their complaints have been legally validated by many countries and have helped to change public attitudes. In most developed countries, homosexuality is no longer seen as a criminal offense and is officially accepted in some institutions, such as the armed forces. A growing number of countries acknowledge same-sex unions and even same-sex marriage.

Internet and Identity Movements

The Internet has become not only a key mobilizing resource for identity movements, but also a means by which identities are promoted and maintained. It has helped movement mobilizations and contributed to the internationalization process of many identity movements, as illustrated by feminist, aboriginal or Islamist social movements. The Internet created virtual spheres that contributed to foster the creation of cultural identities and to support identity movements, especially in urban environment (Castells, 2010). The Internet is at the heart of the diffusion process or diffusion dynamics in social movements, especially along identity issues. It contributes not only to the mobilization process itself, but also to diffuse ideas and values.

As mentioned by Givan et al. (2010), adaptation, political learning, and creative borrowing are vital to social (and identity) movements. Radical Islamists used the Internet to protest against 'the invasion of Western values' while others used it to promote democracy in their countries. Activists against capitalist globalization used the Internet to mobilize people in order to promote global justice (Moghadam, 2009). The Internet explains why some identity movements have a large diffusion outside national borders.

Universalism versus Particularism

Identity movement and the associated communitarian philosophy view values as being interwoven with specific cultures (Touraine, 1997). Symbolic representation is central in identity movements. Rituals, markers, and symbols – such as flags, placards, color (black for activists, red for the leftists), cloths, even music (see Eyerman and Jamieson, 1998) – are important in these movements and collective action and they help create a sense of belonging and establish a distance vis-à-vis others, as it was the case for the union movement. Mineworker locals in the United Kingdom developed their own banners and brass bands.

Some analysts worry about the negative consequences of cultural relativism underlying certain demands put forth by identity movements (see Boudon, 1999; Hardin, 1995). These critics emphasize that communitarian norms easily converge with the interests of the actors involved in identity movements, whereas universal norms seem to be weaker and

take more time to surface because they do not serve the immediate interests of individuals.

For other analysts, countries and modern constitutions today have no option but to accept and make the most of cultural diversity (Tully, 1995). Multiculturalism – which has three different meanings and refers to a sociological reality, a philosophy, or a state policy – must be held up as an example. Multiculturalism does not split society up into isolated subgroups but, on the contrary, offers a common framework within which differences may blossom in a context that respects diversity (Kymlicka, 1989).

Identity Offline and Online

Abstract

There are many approaches to understanding identity, although dominant in critical, cultural, and scholarly contexts are those that understand identity to be constructed or constituted through available discourses and communication methods. Today, that includes the realm of digital Web 2.0 communication. This has complexified the ways in which we can understand the cultivated forms of identity: interactivity, networking, and social networking are all significant factors that change how we perceive the self and its cultural markers. This article provides an overview of the ways in which identity is constituted in off-line and online communicative environments. The article begins with a brief summary of the emerging and current theories of identity and subjectivity; an analysis of the ways in which identity has been discussed as fluid in text-based virtual reality Web 1.0 contexts as well as the shortcomings of such views, and the way in which Web 2.0 sites, emphasizing social networking, present us with new ways in which to think about the production and performance of identity.

Identity and Digital Environments

Identity is one of the most complex facets of everyday communicative engagement, and there are many approaches to understanding the relationship between media, technologies, communicative environments, and subjectivity. However, despite the range and efficacy of theoretical approaches to identity, everyday perceptions of subjectivity and selfhood persist, particularly those which operate within Enlightenment understandings of actions, thoughts, and desires emanating from an inner identity core in which identity is thought and felt to be essentialist, fixed, and innate.

Identity incorporates subjectivity, which is the sense of self as produced through various cultural, political, legal, and linguistic formations, and discrete facets of identity that are intelligible through common demarcations that include gender, race, ethnicity, nationality, sexual orientation, as well as other facets of everyday and political life such as religion, occupation and career, political and partisan affiliation, class demarcations, particular choices in taste and fashion, and the identifications which are produced in everyday relationality with a network of friends, colleagues, acquaintances and significant others in relationships, and in kinship with immediate and extended family.

Core to identity, then, is the broad array of communication methods, channels, forms, texts, interpretations, audiences, and modes of reception. This is the case for two reasons: the cultural and discursive means by which markers and forms of identity are made sensible in discourse, culture and language are mediated (accessed, received, and interpreted through media and communications technologies) and the relationality and forms of mutual identification and recognition that may occur among a group of subjects may at times be face-to-face, embodied and rely on linguistic verbal communication but, at other times in the contemporary era, depend on traditional and new technologies of communication, from the telephone and television to Internet, world wide web, and social networking. Given the increasing contemporary first world ubiquity of digital technologies for communication, there has been some impact on the ways in which we 'do' identity and the ways in which identities are made intelligible to us. However, that is not to say that digital communications technologies and online worlds have wholly changed the methods by which identity is performed; rather, there is a clear – if complexified – articulation between off-line embodied and corporeal communication forms and online digital media technologies and its uses in the context of identity.

Theories of Identity

Modern identity emerged in Western Europe and Great Britain during the fifteenth and sixteenth centuries, culminating in the humanist figure of the free and autonomous individual in the eighteenth century era of Enlightenment. Humanist notions of subjectivity, as Elizabeth Grosz points out, provide the subject with unquestioned certainty, truth, and presence. Central to the contemporary, everyday and 'common sense' understanding of identity and selfhood is the fifteenth century notion of René Descartes (1596–1650) known as the *cogito ergo sum* ('I think, therefore I am'), which operates as a first principle for the idea of an 'I' as a conscious and reasoning individual in which thought or 'mind' is given preference over corporeality and bodily sensations. Significant in western thinking on identity, this notion of the autonomous, coherent, unified self was extended and solidified by numerous writers and thinkers, including John Locke (1632–1704) who posited the liberal and free individual; Jean-Jacques Rousseau (1712–78) who argued for a human individuality grounded in nature; and Immanuel Kant (1724–1804) who equated selfhood and consciousness.

However, although the notion of the unitary, autonomous, coherent and essentialist subject remains the commonsensical and everyday understanding of identity, theories, and philosophies of identity emerging throughout the twentieth century have put this notion of identity in question, and rejected the idea of subjectivity as a self-contained being. Several competing theoretical positions lead to the decentering or rejection of the humanist subject in poststructuralist queer theory. Marxism refuses recognition of the subject as a 'conscious' subject,

attributing it a 'false consciousness' in a capitalist social–economic system. The structuralist–marxist critique of subjectivity undertaken by Louis Althusser (1971) questions the integrity of the universal subject by showing it to be bound by its interpellation through institutions and ideology. In Sigmund Freud's psychoanalytic critique, the discovery of the unconscious fragments the subject at the point of its consciousness, and suggests that one's identity is bound by one's desires. Jacques Lacan (1977), extending Freud's theory through structuralist semiotics, makes clear that desire and subjectivity are inseparable: there cannot be a subject without a concept of desire – in coming in to language in the Symbolic, identity is separated from the unconscious Other, thereby resulting in a subject that is always described as 'split.' For Lacan, desire is constituted by lack as a result of the inability to reacquire the preoedipal and premirror stage *jouissance*, hence the subject (always unsuccessfully) seeks fulfillment by trajecting desire toward the *objet petit a* (another object-of-desire) be it a sexual object, a 'personal goal,' or otherwise – a desire that can never be satiated. Thus, the psychoanalytic approach always posits a subject which is always 'in process.'

From the 1960s and 1970s, the Enlightenment humanist notion of subjective identity was put further in question by theories of social, cultural, and discursive constructionism in which the subject is not born or the result of nature, but produced within the environment, language, and sociality. Both building upon and rejecting the dominant psychoanalytic critique of identity, this anti-subjective structuralist and post-structuralist criticism has become the prevailing understanding in critical and cultural theory of identity, although has by no means resulted in a wholesale rejection of the Enlightenment figure of the subject in contemporary everyday and pedestrian thinking about identity.

Significant among constructionist approaches to identity is the work of Michel Foucault (1926–84) who posits identity not as an 'effect' of power, disciplinarity, and biopolitics, which include processes and techniques of surveillance and normalization. Foucault's theory of subjectivity as a *form* constituted in and by discourse approaches a poststructuralist position – and contributes heavily to it. For Foucault, the subject is inculcated by and through the deployment of power relations, normalized variously in accord with regimentary, disciplinary, and biopolitical discourses. The humanist subject of Descartes as self-existent, coherent, and consciously active is rejected in a Foucauldian position in favor of the disciplining of bodies made 'docile' (Foucault, 1977) and conforming. Three modes of objectification of identity in Foucault's work can be identified: the first is dividing practices, such as the isolation of 'the mad' in asylums. Second is the Foucauldian concept of 'scientific classification' arising from modes of inquiry given the discursive status of science. In the context of Web 2.0 digital media environments, we might similarly refer to this as profile categorization or 'naming'; a discursive practice which in Foucauldian analyses of identity plays a pivotal role in the inculcation of the subject *as* subject. Finally, there is 'subjectification,' the processes 'of self-formation in which the person is active' albeit with conformative regimes. Biopolitics is a technology of power that both analyses and constructs not the individual subject, but whole populations as subjective through a range of techniques from statistical measurement to health promotion to immigration controls; its governance mechanics are generally but not always located within the administration of the nation-state. Emerging slightly later than discipline in the second half of the eighteenth century as part of the further developments of governance for larger states, it is a technology that can be a useful tool for understanding the relationship between online environments and identity in that the use of digital communication tools results in the capacity for large-scale data collection on the level of whole populations, thus producing certain forms of identity which are normalized not along the disciplinary normal/abnormal distinction but in the terms of distance from a norm along a distribution curve of normativities (Foucault, 2007).

Building on the work of Foucault (although at times deploying Lacanian psychoanalysis), Judith Butler projects one of the most useful poststructuralist theorizations of identity by suggesting that the subject is constituted by repetitive performances in terms of the structure of signification that produces retroactively the *illusion* of an inner subjective core (Butler, 1990). Identity/subjectivity becomes a normative ideal rather than a descriptive feature of experience, and is the resultant effect of regimentary discursive practices. The subject, then, is performatively constituted by the very 'expressions' that, from a humanist position, have been considered the essential subject's subsequent conscious actions. As Butler notes, 'performativity' is not a singular, deliberate, and self-conscious act, but a reiterative and citational practice in which discourse produces identity as its effect in a form which stabilizes through repetition over time, but remains always at risk of showing itself up by the constitutive failure of genuine repetition. For Butler, discourse remains the key to subjectivity; but her extension of Foucault's thesis provides a less universalized account of subjectivities. Butler has taken great pains to point out that her theorization of performative identity does not suggest a conscious performance with all the agency that would be accorded in a humanist account (Butler, 1993).

Although Butler's work is complex and wide-ranging, there are four significant elements in understanding how identities can be understood as performative. First, following Nietzsche and Foucault, Butler articulates identity not as static or essentialist but as an *effect* of a performance that is constituted in and through language, discourse, and culture. Secondly, identity or selfhood is performed reiteratively as a process 'in accord' with a discursively given norm or a set of norms. Through the ongoingness of performance of the cited signifier or norm, a subject stabilizes himself or herself by producing a fiction of a fixed, inner, essential selfhood, or subjectivity – this fiction is a retroactive production of an illusion that there is a core identity behind the performance, a doer behind the deed – actions and performances do not stem from an inner essence but retrospectively constitute it. Thirdly, identity is constituted in discourse and can therefore be reconstituted or reconfigured differently in the encounter with different, alternative, emergent, or imaginative discursive arrangements. Finally, the motivation to be articulated as a coherent intelligible self stems from a cultural imperative to perform identity in terms of coherence, intelligibility, and recognizability in order to be permitted belonging and social participation, thus to forge a sense of self and belonging across an array of identity categories or coordinates – which include common axes of

discrimination such as gender, ethnicity, ability, and age, but might also be comprised of spurious experiences that are less easily categorizable and less well demarcated in an identity/difference dichotomy. For Butler, then, identity is manufactured in and through the languages, concepts, and ideas available to a culture at a specific point in time, meaning that in today's media- and digital-saturated western environment, certain practices of communication that are both off-line and online, both transmissional and ritualistic in their use, are highly implicated in the production of identity.

Butler's theoretical account of the performativity of identity puts both liberal-humanist essentialism and postmodern radical constructionism into question in favor of a Foucault-driven anti-foundationalist view of identity. The essentialist/constructionist debates are best delineated by Butler, who points out (1993: p. 8) the ways in which both sides have missed the point of deconstruction by refusing "the constitutive force of exclusion, erasure, violent foreclosure, abjection, and its disruptive return within the very terms of discursive legitimacy." While the essentialist position, for Butler, is both Cartesian and phallogocentric, constructionism leaves a residual essential subject on which cultural construction (sometimes referred to as 'socialization') overlays ideological concepts and gets them 'wrong.' She also identifies an overly radical constructivist position which not only dislodges the essential subject but also makes a claim to the constructive composition of all objects. She argues (1993) that this position understands culture as exhaustively constituting identity, ultimately creating and determining it in its naming that which it names, or, rather, it is that kind of transitive referring which names and inaugurates at once. Her answer to these two positions is to dislodge both the fixity and foundationalism of essentialist views and the determinism of the radical constructivist position in favor of performativity as establishing the subject as *effect* and, more specifically, viewing the subject as a process that stabilizes to produce the effect of fixity over time.

Cultural theorist Fredric Jameson (1985) is correct to point out that in a postliberal or postmodern culture not only is the individual bourgeois subject a thing of the past, but also that in a poststructuralist position "it *never* really existed in the first place; there have never been autonomous subjects of that type." For Jameson, the autonomous subject has been a cultural mystification which sought to persuade people that they actually have an individual and autonomous personal identity. However, despite such theoretical decentering of the subject, the Enlightenment liberal-humanist figure of the coherent essentialist subject remains the key means by which identity is defined in everyday and pedestrian practice in both online and off-line contexts. The mainstream cultural production of identities that are heavily focused on limited practices of individuality manifests within a postmodern framework of problematized self-knowledge, valorized human potential, destabilized social hierarchies, and flexible identity categories. Despite these conditions, a unitary self remains one of the most basic realities premised on notions of substantive identity and perpetuated by dominant medical, legal, and political discourses. A tension thus arises between essentialized notions of identity and more poststructuralist understandings of its constitution; and this discord is reproduced across multiple institutional and theoretical practices, including social network use and its theorization. In effect, identities develop, stabilize, and fracture across multiple, often incongruous discourses, experiences, and technologies.

Virtual Realities and Virtual Identities

Theories of the role of the Internet in critiquing and addressing identity (or in providing opportunities to move beyond Essentialist notions of subjectivity) are many, and emerged in the mid- to late-1990s. Several theoretical approaches that focused on cyberculture sought to examine the role of new technology on the formation of subjects, subjectivity, and identity. The reciprocity of influence between computers and humans gave rise to the emergent field of enquiry known as cyberculture. Early uses of the term were often quite narrow in their definition or utopian in their intent. For example, Mark Dery (1992) focused on the subversive and oppositional forms of identity that emerged in early Web 1.0 Internet use, while Howard Rheingold (1993) presented an idealistic conception of harmonious online virtual communities.

Cyber theorist Sherry Turkle (1999) contends that theories of self that consider the self as largely decentered, such as Mark Poster's approach to anonymous speech on the Internet as being without limits, gender, religion, ethnic, or national requirements, face a constant disjuncture between theorizations of unitary identity as an illusion and, on the other hand, lived experience in which the unitary self is popularly felt to be the most basic reality (Turkle, 1999). The Internet, particularly in the form of early Web 1.0 text-based chat rooms, offered technological objects-to-think-with that allowed postmodern understandings of identity as multiple and always decentered to be explored by facilitating experiential understandings of the illusion of a unitary self (Turkle, 1997). In the often anonymous environments of text-based virtual-reality multi-user domains (MUDs and MOOs), one could invest in and construct oneself in a simulated environment understood to be free of embodied territorial constraints. In effect, one could challenge the idea of unitary identity through the willful experimentation with identity categories. Turkle (1999) gives the example of a user known as Case: a male industrial designer who maintains a 'Jimmy Stewart versus Katharine Hepburn dichotomy' of online personae to exemplify a notion of identity as distributed and heterogeneous, facilitated by text-based online forums. For Case, presenting himself as 'Katharine Hepburn types' online is seen to allow for an externalization of an aspect of himself that he is unable to fully explore in 'real-life' masculine embodiment. Examples of identity play such as Turkle's are problematic for two reasons. First, they maintain the real-world/virtual-world dichotomy that is pervasive in much cyberculture and mainstream discourse of online communication and social networks. The dualism of the human and machine boundary is far less discernibly established and may be more usefully described in terms of a series of performances across a socio-technical network wherein the 'interface' consists of a multiplicity of aligned and dynamic encounters between different configurations, including as persons and machines. Examples of identity play and identity fluidity through the utilization of

online sites, such as Turkle's exploration of Case, rely on acts self-stereotyping in order to maintain online personae. While not explicitly explored, Case's use of film icon stereotypes highlights the theatricality of his online personae, which fall short of the performative approach to identity espoused by Butler. Although celebrated as examples of identity fluidity, these online performances are thus theatrical and maintain the consistency and coherence of off-line embodied identity, rather than being a genuine challenge to prevailing everyday concepts of unitary and essentialist identity.

Resulting from the increased materiality afforded to multiple and divergent identity category expressions online, it is understandable that early cyberculture theorists postulated a future where the unbridled expansion of identity categories might lead to a utopian world wherein 'identity' could be extricated from foundationalist principles. What the success of a social network like Facebook might suggest, though, is that all of the identity 'choices' presented online necessitate a mediatory tool if one is to readily articulate a coherent and intelligible self and present a picture of selfhood for the scrutiny of a plurality of gazes. However, despite the shift from early anonymous text-based communication, Turkle's early work remains helpful in framing the possibility for some technologies to impact 'older centralized ways' of considering identity. Within Turkle's framework, objects anchor experience and memories. So while her example of Case's online personae is problematic, it is nevertheless helpful in highlighting how objects contribute identity construction.

Digital Communication, Social Networks, and Relational Identity

Many current approaches to understanding the relationship between Web 2.0 environments (characterized by YouTube, Wikis, and – most particularly – the social networking sites such as MySpace and Facebook) are grounded in the notion of social network use as emanating from a coherent a priori self (e.g., Donath and Boyd, 2004; Liu, 2007; Livingstone and Brake, 2010), despite the powerful arguments put forward within poststructuralist theory that 'show up' the possibility of a genuinely coherent, intelligible, and unified self (Cover, 2012). Although, from a Foucauldian, Butlerian, and post-structuralist perspective, all performance of identity is relational in that it requires the citation of discursive categories of identity, is performed for recognizability, and operates within constructed 'truth regimes,' the relationality of Web 2.0 digital media and communication environments further implicates identity within a network of others in which mutual surveillance can be understood as the key to identity articulation in an online environment – a surveillance in which online users are always from the beginning complicit. Identifications and categorizations online thus function to assert individuality and often involve a process of stereotyping that allows group members easily to distinguish self, others, and group members (Buckingham, 2008).

Much of the early current literature on social networks describes the conscious, willful *use* of an online technology like Facebook. This position is coterminous with early cyberculture work that maintains the 'real-life' versus 'virtual self' dichotomy and, effectively, the reification of a 'real' identity out of which the 'virtual self' could be voluntarily created. However, several more effective and theoretically-grounded approaches to understanding the relationship between social networking and identity build on the work of Erving Goffman (1959). Goffman's dramaturgical analysis of identity performance offers a convenient framework for the analysis of identity expression only. Social networks, situated in the broader cultural practices of individualism, self-narration, and interconnectivity, offer many parallels to Goffman's work. Goffman points to the self-conscious presentation of selfhood in different contexts as well as the symptomatic elements of performance – that is, what people 'give' and what they 'give off.' An individual, for Goffman, performs identity through both of the forms of intentional and unintentional expression. In the context of social networking and other online forms of relationality, Goffman's approach to the performative expression of selfhood points to the ways in which the online acts of typing, updating, uploading photos and videos, and other activities serve as both intentional and unintentional forms of expression to varying degrees depending on intent and context.

One way in which we can understand the use of social networking through Goffman's concept of 'everyday performance' is through what Hugo Liu (2007) refers to as 'taste performances.' A taste performance is the textual statement of a socioeconomically and aesthetically conditioned taste that conveys 'prestige, differentiation, authenticity, and/or theatrical persona.' Within Liu's Goffman-derived framework, taste performances are voluntarist acts whereby performers are broadly aware of the impressions they foster among viewers. That identity can be cultivated by and through taste performances points to the ways in which the expression of tastes, which can best be seen today through Facebook 'likes' and the listing of particular favorite films, activities, television, and music in Facebook profiles, are not only relational in that they are deliberately communicative but also relational within a neoliberal consumer culture that has brought consumer choices to bear upon the production of self-identity.

Liu's exploration of taste performances on social networks is helpful in two ways. First, by framing identity coherence as a strategically-expedient outcome, Liu highlights a tension that social network use can produce – that is, between expressive coherence and the potentially destabilizing role of an audience that scrutinizes (in)consistencies in the ongoing performance of selfhood through the linearity of taste. Secondly, Liu draws attention to identities increasingly constructed around a growing number of possible consumptive choices – effectively, individual identities are increasingly enfolded in a collapsing between consumption and the performance of taste.

These conclusions, while helpful, are problematic in that Goffman's framework reinforces the notion of (and hides the constructedness of) a core essentialist self from which tastes are seen to emanate. Effectively, taste performances are presented as *external* representations of identity expression, thus maintaining the power mechanism of categorization in identity formation. Taste performances, however, are not merely representations, but can be seen to construct the identity or self [that is] perceived to be making those decisions (Cover, 2012). The stability of a retroactively constituted performative identity

is thus problematized when narrowing boundaries of identifications produce more opportunity for misrecognition and require greater online 'identity work' (performativity) to sustain. Additionally, the implication of Liu's analysis is that as the available system of possible taste performances becomes more complex, so too do identities as they increasingly combine these performances in new and divergent ways.

While Liu explored the expressive potential of listed cultural interests online as taste performances of identity, Donath and Boyd (2004) have investigated how social network users' friending behaviors and the public display of friend networks contribute to identity portraiture and performance where networks of displayed connections between related groups form integral parts of self-identity. They point to the way in which we can understand two features of the architecture of a social network such as Facebook, however, as having implications for the stable performance and coherence of identity – connections that are both 'unnuanced' and 'decontextualized.' Connections can be viewed as unnuanced as there is little, if any, distinction made between, say, a work colleague, a lover, close relatives, and others who are grouped under the category of 'friend.' Connections are also largely decontextualized in that one's network is usually viewable in its entirety. Donath and Boyd (2004) frame identity work on social networks as willful, representational repair work to 'save face.' This implies that 'incompatible texts' – taste performances and connections – stem from an incongruence among external, representational texts that operate from an a priori core. External performance, 'giving off,' is destabilized by contestatory taste performances or incompatible connections, but the prediscursive self from which these performances emanate remains intact.

From a Foucauldian perspective, power mechanisms operating through social networks rationalize a sense of a prediscursive self and mask the unconscious performativity of identity. These mechanisms can be said to include the discursive conditioning of identity categories, self-recognition through a process of interpellation and the internalized practice of self-surveillance, as well as the active (and relational) surveillance of others. Drawing on Judith Butler's theories of identity performativity, Rob Cover (2012) investigated the distinction between profiles and relational groupings in social networking sites, indicating the ways in which the confessional forms of self-disclosure made by users through profile selections and statements conflict at times with the surveillance of social networking 'friends' whereby surveillance is no longer merely disciplinary and modeled on the panopticon but has shifted into a network morphology. However, the fact that social networking sites record a person's history of statements, tastes, relationships, friendships, confessed activities, and responses from others produces an 'archive effect' which is precisely that which opens up the possibility of identity incoherence in cases where the repetition of tastes, performances, relationalities, and articulations is not repeated or consistent with the user's past.

Online Identity and New Technologies

There are three elements to understanding online identity, as divergent from Enlightenment forms of identity experienced prior to the age of the Internet, that emerge from a Foucauldian–Butlerian poststructuralist approach: new relationalities; new forms and processes of self-categorization; and new forms of surveillance. In each case, these indicate the ways in which digital technologies have, on the one hand, opened up new mechanisms for the coherent performance of the (mythical) unitary and autonomous self and, on the other, point to the constructedness of identity.

Relationality

According to Turkle (2011), online networks promote multiple, simultaneous, and mediated interactions that reduce critical reflection and can lead to isolation anxiety; the more we control these interactions, the less we are able to cope with the uncontrolled situations, like a conversation. If an object such as Facebook affects us psychologically, then being connected yet experientially alone means that identity construction is becoming increasingly relational, built on high quantity, low quality interactions. While Facebook reiterates these relations as stemming from a unitary self, and with clearly delineated categories of identity (of say gender), the unconscious performative 'self' in this environment is less critically aware, more connected, more anxious, and more concrete (and controlled) in both the expression and feedback of aspects of self. This further complicates the construction of a unified cohesive self as identity becomes increasingly contingent on technology that simultaneously catalyzes and problematizes identity coherence.

Categorization

One of the central mechanisms in Butler's (1990) analysis of performative identity is the role of categories. The construction of identity categories – gender, race, nationality, and so forth – as coherent and stable, produces identity within regulatory regimes and a reification of identity categories as normative statements. For example, the stability and coherence of categories such as 'male,' 'woman,' and 'heterosexual,' rely on normative discursive frameworks that regulate the field of their intelligibility. While some categories like 'woman' or 'heterosexual' achieve their stability and coherence within the heterosexual matrix and are predominantly naturalized and unproblematically invoked, other identity coordinates like race, class, ethnicity, or nationality are less stable and less accepted. What is important about the mechanism of categorization is that it functions within a representational discourse where categories operate as domains of exclusion and produce 'coercive and regulatory consequences' of their construction.

Social networking sites can be understood as sites through which identity categories are effectively performed. Most social networks are built around individual user profiles. The first step for the creation of any given profile is to engage in a form-filling process; a process that now occurs countless times over one's lifetime. As Butler notes, the repeated act of 'naming' identity categories is an institutionalized form of regimentation that produces and circulates normativities by requiring the construction of identity in accord with dominant discursive arrangements like heteronormativity and naturalized principles of sexual difference. As initial profile creation frequently

involves submitting gender and age, and often includes sexual preference, nationality, and relationship status, it can be viewed as a set of acts that are repeated over time and produce a mythical reality.

Therefore at a deeper level of analysis, the ritualistic practice of form filling, under a new pretense of social network profile creation, cannot be merely the conscious process of 'biographization' (Livingstone, 2008). Rather, the repeated 'naming' of each category operates as a performative that stabilizes both the category itself and its appearance of coherence within an individual. By continuing to operate within the same framework, though, expansive identity categories remain representational social fictions to which one can be held accountable. As Butler (1990) notes, no one category can be fully decontextualized from other axes of power relations – such as race, ethnicity, and class – that together constitute identity and prove that no singular facet or notion of identity can stand for the subject altogether. Thus as the sophistication of differentiation within a system of categorical axes of power increases, so too does the individual requirement to work at their adherence to categorical norms. Social networks therefore exacerbate an existing tension between reified notions of singular identity and the impossibility to achieve complete adherence to categorical norms.

Despite this discord, an effect of this perpetuation of the mechanism of categorization is the normalization and stabilization of identities. As the reiteration of norms stabilizes over time to produce the effect substantial identity, power mechanisms of social networking are able to effectively coordinate the articulation of a coherent identity. As noted, form-filling, profile creation, and network management function to sustain gender as a naturalized foundational 'fact' of one's identity. For example, in order to join Facebook one must select a sex. While instances of misrecognition or nonidentification within the sex binary may occur in individuals who do not self-describe as belonging to either category, the force of disciplinary power within medicolegal discourses maintains the fundamentalism of sexual difference. For a subject who is unable to comply with the 'available' categories, not only is there the off-line risk of being classified as a nonperson, but also the online risk of not being able to be a Facebook user.

Surveillance

However, the existence of categories does not in and of itself ensure that they are accepted. In Foucault's framework of a disciplinary society, dominant discursive arrangements are maintained through processes of exclusion and normalized identity practices that are in part sustained by the mechanism of surveillance. The abstraction of the panopticon offers a useful model to examine how visibility imposes on the observed (and the observer) a regime of self-inspection and self-control. However, in the context of the increased visibility of self, social networks' role in surveillance becomes one that is grounded in the nodal points of a relational network rather than the centrality of the panopticon, even though both encourage self-surveillance as the normative function of disciplinary power (Cover, 2012). Specifically, Facebook can be viewed as a tool par excellence for the stabilization of a coherent identity because it expedites the stylized repetition of highly mediated identity categories and 'templates' under increased surveillance. However, this process is by no means unilateral or uncomplicated, and effectively produces the conditions for its own destabilization. We can view surveillance as an internalized process that operates alongside externalized practices of surveillance. When one participates in a social network, the implicit requirement is to produce knowledge about oneself in the form of profiles, statuses, photos, and so forth. Each instance of this production increases one's visibility within the disciplinary system, and potentially amplifies the effect of that system on the construction of identity.

Identity Futures Online

Inasmuch as users are now cognizant of the problem of the multiplicity of the networked audience in terms of who is accessing information, how it is being utilized, the extent to which one might be required to explain oneself to different friends and different groups (Lewis and West, 2009), it may well be the case that the 'identity project' of social networking has an uncertain future. Recent questions and public commentary on digital privacy and the utilization of social networking accounts by third parties who construct marketing profiles based on portions of identity and taste information and usage have both generated and revealed a number of anxieties around social networking as a tool for identity performativity. One question that remains open for future investigation is whether or not users will grow tired of the additional 'identity work' caused by the potential incompatibilities between the friendship network, the constructed profile and any distinction between online and off-line performativity. Or, on the other hand, if this is the start of a new discursive framework in which a culture begins to embrace the complexity and incoherence of identity, leading to the fruition of post-modern and post-structuralist thinking of the self.

Ideological Constraint: History and Current Status of the Concept

John P Connolly, The University of Texas at Arlington, Arlington, TX, USA

Abstract

Fifty years ago, Converse (1964) introduced the principle of ideological constraint. While references to this concept are still prevalent in the political science literature, its import largely rests on one's acceptance of Converse's classic formulation of political sophistication, about which there has been a voluminous literature and persistent debate. Here the origins and conceptual foundations of this concept are reviewed to assess its precise relevance to what it means to be politically 'sophisticated.'

My own belief is that many philosophical difficulties and controversies arise from insufficient realization of the differences between different kinds of knowledge, and of the vagueness and uncertainty that characterizes most of what we believe ourselves to know (Russell, 1948: 439).

Introduction

Reflecting on four decades of scholarship on political sophistication, Robert Luskin claimed that use of the term ideological 'constraint' was 'mercifully fading.' This observation should have surprised many coming from a scholar who was once among the most enthusiastic promoters of the concept, which he had once regarded as the *sine qua non* of political sophistication, as well as the one scholar who attempted its formalization. He noted that various other terms were now being used in place of 'constraint,' such as 'expertise,' 'cognitive complexity,' 'ideology,' 'information,' or simply 'knowledge' (Luskin, 2002: 281).

It has been observed elsewhere, however, that the captivating power of certain ideas can long outlive their value (Keynes, 1997: xii). One question at the outset of any discussion on the topic of ideological constraint then is whether the whole concept in question is a defunct notion, kept alive only by scholarly habits. If so, then obvious questions arise given that so much scholarship has been invested in the topic. For example, where did the concept of 'constraint' come from? Further, when, how, and why did it falter? Last, have more useful conceptions been developed in its place? Or is, what has been called political 'sophistication' reducible to plain 'knowledge'?

To preview the conclusions drawn here, it is agreed that the concept of ideological constraint is indeed anachronistic though this does not appear to be as widely recognized as might be intimated from Luskin's claim. Second, it is argued that the alternative conceptualizations that have been advocated in its place are also deficient. This is largely because a close analysis of these ideas reveals them to be little more than variations on the earlier theme and, despite much apparent debate, do not challenge the conceptual foundations which permeate that theme. Last, while it is tempting to give up on the whole idea of political sophistication and adopt less evocative terminology, such as the more prosaic term, 'political knowledge,' it is held here that there is indeed value in developing a conception of the 'sophisticated' over and above that of the 'knowledgeable' citizen. The final section lays out some of the basic requirements that any such new formulation of political sophistication should meet.

The crux of the argument presented here is that the problem with the classic formulation of political sophistication is twofold: first, it requires one to take a dogmatic position on a long unresolved philosophical problem concerning the definition of knowledge; second, it does not address the development and character of goals and values. It is maintained here that both issues need to be addressed for any new formulation to enjoy wider acceptance than its predecessor.

The Conceptual Origins of Ideological Constraint

The concept of ideological constraint dates back to Phillip E. Converse's (1964) seminal essay on political sophistication. If Kenneth Arrow's (1951) 'Social Choice and Individual Values' was the 'big bang' of social choice theory (a comment attributed to Amartya Sen by Poundstone (2008: 57)), Converse's 'The Nature of Belief Systems in Mass Publics' was the analogous foundational study in the field of political behavior. In neither case is it strictly true that what followed came out of nothing. Just as Arrow's findings had been anticipated by others, Converse's formulation of political sophistication had been anticipated in a number of earlier studies (Campbell et al., 1960; Berelson et al., 1954; Lippmann, 1922; Bryce, 1904). However it was not till Converse (1964) that the concepts of political sophistication, ideology, and constraint, were interpreted as essentially referring to the same thing. Opining that "A term like 'ideology' has been thoroughly muddied by diverse uses," he defined one's 'belief system' as a "configuration of ideas and attitudes in which the elements are bound together by some kind of constraint or functional interdependence" (Converse, 1964: 207).

The analogy with Arrow's famous work holds further in that Converse's formulation also led to a paradox of sorts. In everyday parlance, one may distinguish between the 'sophisticate' and the 'sophist,' between one who undertakes the honest process of factual acquaintance versus one who operates completely in rhetorical space, between a truth-seeker and one whose mind is closed to new discovery. Yet such distinctions

are blurred when the 'sophisticate' is equated with the 'ideologue.' Thus Luskin, arguably the leading disciple of the Conversian tradition, was led to assert that "political sophistication has nothing to do with acuity … John Birchers and Trotskyites alike may be highly sophisticated in this sense. Sophistication is a matter of how much and how a person thinks about politics, not what" (Luskin, 1987: 864).

Whether this *reductio ad absurdum* is actually what Converse intended is not absolutely clear. He had, for example, discussed other attributes of a political belief system (PBS), such as its 'range' in addition to the 'centrality' of the political objects that constitute it. But these concepts were quickly passed over with the core of Converse's discussion focusing on ideology and issue constraint. Thus Luskin was only following Converse's lead in giving overwhelming emphasis to the ideological constraint principle and carrying the concept's implications through to their logical end. Likewise, Luskin's (1987: 882) contention that the whole issue of factual truth was traditionally given 'shorter shrift' is wholly consistent with the classic formulation of political sophistication, even if this point is frequently overlooked both by ostensible proponents and opponents of the Conversian tradition.

In Converse (1964), the word 'constraint' was used in two senses, one psychological, the other social. The first referred to what Converse called the 'logical' or 'quasi-logical' connections between the beliefs that comprise one's belief system, while the second referred to the amenability of one's belief system to socially diffused cues. Converse appeared to argue that the distinction between the two was unimportant as a practical matter. As such, his formulation of a belief system was not new, being a blend of the coherence theory of knowledge and pragmatism, compatible with the respective perspectives of Hegel and John Dewey: in short, that no one belief has any intrinsic credibility on its own account but derives all its credibility based on its relation to other beliefs that, taken all together, constitute a closed system.

Yet if this conception of knowledge was not new, it was still *dogmatic*, since the whole question of how one defines knowledge is a long unresolved problem in traditional philosophy, and there are other definitions that accord more importance to data and facts. As such, there are aspects of the Conversian formulation that should have seemed objectionable at the outset. Why, for example, should one accept a formulation of political sophistication that has, as maintained by Luskin, 'nothing to do with acuity'? What is its justification as a dependent variable worthy of study in political science? Further, what normative value does such a formulation offer? As will be shown, a close reading of Converse's own empirical examples of emerging social movements tended to undermine the whole significance of ideological constraint as an analytically important concept.

Indeed this is where the earlier analogy with Kenneth Arrow's parallel work in the field of social choice begins to break down. For while one was compelled to accept Arrow's arguments due to his strictly logical analysis, there is no such obligation to accept the classic formulation of political sophistication, which is an empirically derived conception. Its acceptance depends crucially on its relevance, coherence and, further, it is emphasized here, on its normative value. The rest of this analysis explores whether this concept has ever met these criteria, and, if not, the lessons that could lead to a better formulation.

Reactions to Converse's Formulation of Political Sophistication

Following Converse (1964), a vast literature on the topic of political sophistication ensued in large part reflecting a desire among scholars to disprove implications they found repellant. However, the culmination of this long-running debate was that research and conclusions began to diverge. If there is less overt debate on the topic today it in large part reflects the fact that those in opposing camps have adopted different terminology so that they often talk past each other, the effect of which may create a false picture of consensus. For example, the topic has, to an extent, been rebranded in terms of political 'competence,' rather than political 'sophistication.' Similarly, Converse's use of the terms 'beliefs' and 'belief systems' is often discarded in favor of the term 'attitudes.' By such means, an uneasy peace gradually emerged between a revisionist camp and those more faithful to the old religion, with tensions between the two only occasionally spilling over (e.g., see Lupia, 2006).

It is not the case then that there has been no debate over Converse's (1964) claims. Rather, and notwithstanding the terminological changes just noted, the debate has been almost exclusively concerned with claims concerning the *distribution* of Converse's political sophistication variable, with little or no challenge to the ideological 'constraint' principle which was at the core of the original formulation. In fact, the direction which ostensible critics of the Conversian tradition took in turn led to yet cruder forms of this same principle and, ironically, depictions of the ordinary citizen that are even less flattering. Meanwhile ostensible defenders of the old religion have added confusion to the debate by focusing on the factual awareness of the citizen, apparently unaware that this was never part of the original formulation.

An ironic consequence of these trends is that it is now the disciples of Converse who, by measuring factual knowledge, offer one possible way out of the paradox noted earlier in which all ideologues are indistinguishable, while it is those most vocal critics of the Conversian school of thought who arguably perpetuate the notion of ideological constraint, albeit with different terminology. The means by which the latter is achieved are diverse, reflecting the voluminous reaction to Converse, but a common pattern is discernible. This is a consequence of the exclusive concern among critics to dispute Converse's contention that the distribution of political sophistication is confined to a very small group of citizens, one implication of which is that control of the polity rests on the mass public's whimsical tendencies.

The most common means to refute this conclusion has been to adopt a different starting point. Rather than beginning with a study of political sophistication at the individual level and attempting to infer the aggregate consequences, the alternate approach begins with the postulate that the polity is as functional as it could be and then proceeds to rationalize what must be happening at the individual level for this Panglossian state of affairs to exist. In its extreme form, this argument holds that the very stability of the polity depends on the fickleness of the

mass public. Here the mind of the average citizen is depicted as a *tabula rasa*, conditioned by how a few innovative thought leaders frame issues, as in Stimson's (2004) Humean account of idea association:

> The first time one sees two totally separate issue positions advocated by one party or candidate, they seem to be just that: two ideas espoused by one source. But as time passes and those two same ideas are repeatedly advocated together, for example, liberalism and choice, then they come to be related. As the process runs to ultimate conclusion, we begin to see the two as two facets of the same thing and think that they are inseparable.
>
> Stimson, 2004: 68–69

Stimson's basic thesis is that, while the public may seem to be fickle on the surface, there is still a 'smooth path from here to there' (Stimson, 2004: xvii). Stimson agrees that "the hope of democratic governance [goes] down the drain" with a citizen "who can't know his or her own preferences," but he reconciles this difficulty by contending that individual opinion is 'thermostatic.' Like the "homeowner with a thermostat need not understand the physics of home heating and cooling … All that is required is to notice 'too hot' or 'too cold' and to send the appropriate signal." Further, he argues, it is the framing of issues in this way – more, less, or same – that makes democracy possible (Stimson, 2004: 32–33).

These claims are in one sense remarkable. Half a century earlier, Kenneth Arrow had demonstrated the unavoidable difficulties involved in aggregating each individual's rational preferences into a noncontradictory collective outcome. In Stimson's account, such problems are held to be empirically irrelevant by the ability of elites to induce limited mechanical reactions from the citizenry. In short, while Arrow undertook the challenge of demonstrating how a democratic polity could operate on the basis of autonomous individuals ordering their own ordered preferences, Stimson's solution is based on the logic that only a small number of people pay attention to politics (Stimson, 2004: 15), and who effectively predetermine the possible orderings of everyone else's preferences.

A similar line of thought is pursued by Lupia (2006). There the question is formulated in terms of whether citizens are 'competent' enough to determine which electoral option best serves their interests. How one's interests and goals are determined – in short, the reference point for one's competence – is taken as given and, as such, goes unanalyzed, a topic Lupia opines is an "inherently normative … complex debate." The proposed mechanism for demonstrating competence then leans heavily on the use of heuristic references to guide one's choices.

In taking issue with the widely held contention following Converse that the mass public is politically unsophisticated, Lupia is especially critical of the means by which scholars have attempted to measure knowledge differentials across the public. In this respect, he distinguishes between declarative and procedural knowledge. "Declarative knowledge" refers to knowledge about facts and things (Matlin, 2005: 264) whereas "procedural knowledge" pertains to one's knowledge "about how to do something," such as "how to ride a bicycle" (2005: 129). It is the latter kind of knowledge, argues Lupia, which is relevant to the question of political competence. From a similar perspective, Prior (2009) has argued that assessments of competence from survey data are over reliant on verbal responses, and also pay too little attention to the motivation level of the respondent (Prior and Lupia, 2008).

Further, it is contended that the democratic ideal of the informed citizen is a fiction and that people are more free to the extent they do not have to engage in political deliberation, since "the more we demand of people, the less freedom they have, and freedom is among the most valuable products that democratic societies can produce" (Lupia, 2006). As such, there is no normative value in having any more knowledge than is necessary to exercise one's minimal civic duties. Knowledge over and above this minimum is superfluous to 'efficient' decision-making.

Such arguments have frequently borrowed accounts of decision-making from the field of social psychology and cognitive science, which have then been employed to give stylized accounts of political behavior, a practice which Krosnick (2002) calls 'psychological political science.' Such research could still in theory lead to 'extensions and revisions of the inspiring psychological theories' (Krosnick et al., 2010: 1289), but this appears to have rarely happened. As argued by Druckman et al. (2009), such theories often undergo an evolution within the social psychology literature while only a crude replica of the original formulation continues to be used elsewhere.

The reflexive resort to heuristics to explain political behavior is arguably a case in point. As Druckman argues, "the very point of heuristics is that they function as an alternative *processing* mode to rational decision-making … Because both are procedural, the difference between them does not depend on the outcome of the decision process" (Druckman et al., 2009: 493). That is, whereas heuristics are understood to be a 'computational' shortcut in the social psychology literature, they have instead been frequently interpreted as an 'informational shortcut' in the political science literature. Thus the contention that the use of heuristics bridges informational gaps is problematic on conceptual grounds.

Yet another way of escaping the unsettling implications of Converse (1964) has been to revive Robert Dahl's classic notion of pluralism. Here the key requirement for a smoothly running 'polyarchy' is that citizens have strong attitudes on at least some issues. In turn, the focus on 'attitudes,' as opposed to 'beliefs,' relegates the whole importance of knowledge differentials. Once again, one's goals and values are taken as given and go unanalyzed, serving only in determining the 'importance' of an attitude (Boninger et al., 1995). A kind of political equilibrium then ensues reflecting the public's diverse preferences, here via the interaction of a multitude of interest groups. Converse (1964), himself, had opened the door to this line of thinking with his discussion of 'issue publics' toward the end of his famous essay. Yet attempts to revive the classic concepts of pluralism and polyarchy are somewhat strange in light of misgivings expressed by Dahl, himself, in his later ruminations (Dahl, 2003, 1986).

The foregoing point concerning the use of social psychological theories in the political science literature is especially salient with respect to the concept of ideological constraint. According to Krosnick, Converse's original formulation was

inspired by then contemporary theories concerning cognitive dissonance and cognitive consistency (Krosnick, 2002: 191). In turn, one might depict the political 'sophisticate' as she or he who best performs dissonance reduction. However, the theory of cognitive dissonance has undergone substantial reformulation and qualification since it was introduced by Festinger (1957), with the process of dissonance reduction now understood to be triggered by threats to the self (Kunda, 1990). Yet the corresponding concept of 'constraint' in the political science literature has not undergone any parallel refinement that could potentially rescue it from its own internal ambiguities and contradictions.

A Formalization of Ideological Constraint

Luskin (1987) offered a formalization of ideological constraint which is noteworthy in several respects. First, the implications of this formalization are themselves surprising, in that they seem to make the connection between ideology and constraint somewhat ambiguous. Second, Luskin, arguably the most enthusiastic advocate of ideological constraint as the essence of political sophistication, was later to comment that invocations of the very principle he had attempted to formalize were 'mercifully fading' (Luskin, 2002: 281).

Expounding on the terminology of Converse (1964), Luskin's analytical framework is that of a PBS comprising various cognitions. As such, he defined a PBS as varying along three dimensions: size (the number of cognitions), range (the coverage of the political universe), and constraint, which is "the extent to which the PBS's cognitions are interconnected" (Luskin, 1987: 859). With respect to the individual cognitions, their value is solely in terms of their relationships to other cognitions, not whether there is any factual correspondence to the outside world. This could be viewed as a model of one strain in traditional Western philosophy that defines knowledge solely in terms of connections between beliefs, and not in the truth value of individual beliefs.

What distinguishes a cognition is its centrality; that is, its importance relative to other cognitions. As such, Luskin defines the centrality of the ith cognition in a PBS of N cognitions as follows:

$$m_i = \frac{1}{N-1}\sum_{j=1}^{N} c_{ij}\frac{1}{d_{ij}}$$

where $c_{ij} = 1$ if the ith cognition is directly or indirectly associated with the jth and is zero if not, and d_{ij} is the 'minimum number of intercognitive links to get from the jth cognition to the ith.'

Then Luskin defines the constraint, 'C,' of a PBS, as the proportion of all possible pairs of cognitions in which elements of the pair are directly associated:

$$C = \frac{1}{N(N-1)}\sum_{i=1}^{N}\sum_{j=1}^{N} a_{ij}$$

where $a_{ij} = 1$ if the ith cognition is directly connected with the jth and is zero if not.

In short, Luskin asserts that a maximally constrained PBS is one in which every cognition has a direct link with every other cognition. This is a somewhat surprising formulation in that it points to a mesh configuration as indicative of the constraint principle, in which all cognitions have the same centrality. As such, the idea of constraint, which notionally seemed to correspond to the concepts of efficiency and organization, turns out to be one whose characteristic feature is redundancy.

Yet what is perhaps more noteworthy here is that all cognitions are equally central in the mind of a sophisticate; in short, the political sophisticate appears to entertain no doubt whatsoever. Such a formulation seems questionable. What one comes to know about politics comes from all different kinds of sources and involves all kinds of different inferences. As such, the connections between some beliefs may come close to the status of deductive logic while others are likely to be much more tenuous. It seems questionable that any rational individual could possibly think about politics in the way implied by Luskin's model of the sophisticated mind; that is, be equally certain of every idea in one's head.

There is a related ambiguity here. Luskin's model suggests a direct trade-off between having a large, differentiated belief system, as opposed to a 'constrained' one. But it is not clear why the latter should be preferable as a rule. The appropriate level of cognitive abstraction in any given political situation must always be context-dependent, whereas it is implied here that thinking in static, abstract terms is always preferable.

What Did Converse Actually Demonstrate?

The debate following Converse (1964) largely centered on the question of whether the distribution of political sophistication – the essence of which has been understood to be 'ideological constraint' – is largely confined to a small segment of elite thinkers or is instead more widely dispersed across the mass public. Yet, regardless of this question, Converse's own analysis of the role of ideology in the case of two notorious social movements appeared to downplay its whole importance.

In his first example, Converse reviewed the emergence of the Nazi party in early 1930s Germany. His main motivation here, perhaps, was to address the whole question of how an informed citizenry could have let the Nazis take over the country. However, his discussion provides little insight here. One difficulty might be noted at the outset in the wider context of his formulation of political sophistication: If the essence of sophistication is in being ideological, and if ideology is, according to Luskin (parodying Gertrude Stein), "an ideology, is an ideology" (Luskin, 1987: 863), then on what grounds does one critique Nazi ideology? In fact, Converse, himself, ridiculed the whole importance of ideology in the case of the growing popularity of the Nazis, arguing that its supposed relevance 'verges on the absurd' (Converse, 1964: 254), and asserting that "Even had the clientele of the Nazi Party been of average education and political sophistication, there would be strong reason to doubt the degree to which prior awareness of Nazi ideology among its voters could be claimed" (1964: 254).

Converse reasoned instead that the German public was mainly responding to concrete proposals to improve its plight in economically desperate times, and no other political organizations were making such efforts to win support, especially in Germany's rural areas (Converse, 1964: 253): "The Nazis

promised changes in a system that was near collapse. Under comparable stresses, it is likely that large numbers of citizens in any society … would gladly support *ad hoc* promises of change without any great concern about ideological implications." Converse opined, in turn, that history might have been quite different and the key to this is that voters were open to other appeals; however, opposition party elites failed to reach out to the mass public and offer such alternatives. Would it have been better if the German public had been more socially 'constrained'? Converse offered no such argument and, in fact, the whole question seems inherently ambiguous.

While Converse's first empirical example argued that ideology was irrelevant in the case of the emergence of a social movement aimed at *bad* social ends, his next example – the emergence of the abolitionist movement in nineteenth-century America – appeared to show the irrelevance of ideology to the success of a social movement aimed at *good* social ends. In that case he argued that beliefs in abolition played very little role in developing the mass base of the Republican Party citing, again, other more concrete factors, such as the promise of free land in the West and the impact of the railroads. As such he held it doubtful that the ordinary non-Southerner in 1855 betrayed any concern for abolition (Converse, 1964: 250–251).

What these two empirical examples seemed to demonstrate was that ideology played little role among the mass public at the outset of social change, whether for better or worse, and that the ideas providing the impetus for social change originated from a relatively small segment of society. Yet even if this insight has wider application, it would still be inadequate as an account of social change since it overlooks the extent to which some ideas subsequently come to resonate with the public more than others. Do, for example, the ideas, beliefs, and values promulgated by the Nazis have the same cognitive status as those promulgated by the abolitionist movement? If it is true, as suggested by Stimson (2004), that the apparent connections between political issues are arbitrary and ephemeral then the whole idea of progress is arguably moonshine and the question of one's goals and values has no relevance to political sophistication. However, if progress is not illusory, then the nature of one's goals and values, not merely one's attitudes and beliefs, must be equally important.

Conclusion

To summarize the key points thus far: First, Converse's formulation of political sophistication was a purely empirical derivation. His justification for attaching any importance to the variable he discovered was solely in terms of considerable observed variability, claiming that "the variation in constraint as a function of sophistication or involvement is extremely large: There are no other discriminating variables that begin to separate populations so cleanly and sharply as these measures" (Converse, 1964: 233). No explicit concern was expressed as to the consequences of this variability and his empirical examples did not demonstrate any benefit in having a different distribution of ideological constraint across the mass public. As such, to the extent the variable he identified, what has since come to be known as 'political sophistication,' has been ascribed any normative value, a naturalistic fallacy of sorts has been committed.

Second, although there has been much apparent debate in reaction to Converse (1964), it has centered almost entirely on whether Converse's variable is more widely distributed than he initially claimed. As such the notion of ideological constraint, which was central to his formulation, has gone unchallenged. This fact is sometimes disguised by the use of different terminology; in particular, the terms 'competence' and 'attitudes' are often substituted for 'sophistication' and 'beliefs' respectively. Yet despite the diverse terminology, a common pattern is discernible in the reactions to Converse (1964). Whereas Converse began with an analysis at the individual level, the critiques of sophistication scholarship typically start with the assumption of a smoothly running polity and then propose a model of what could be happening at the individual level for this Panglossian state of affairs to exist.

Such critiques are in fact focusing on what Converse regarded as the social sources of constraint. But whereas Converse (1964) had suggested that the mass public was not socially constrained, those on the other side of the debate have proposed mechanisms by which it is. Clearly, such reactions do not then present a challenge to the constraint principle but, arguably, serve as a recapitulation of it. In turn, the critics of sophistication scholarship have pushed a normative conception of the citizen as one largely detached from the world of politics but who can perform his or her duties in an 'efficient' manner. In its extreme form this latter formulation holds that requirements for political participation and involvement are an obtrusion into civil society and therefore an impingement on one's freedom.

Third, since the ideological constraint principle remained substantively intact from the criticisms in reaction to Converse (1964), it follows that there has been no resolution to the *reduction ad absurdum* in which sophisticates are not in any way distinguished by the truth content of their beliefs, and according to which all constrained belief systems are treated as equally indicative of sophistication. As such, the political sophistication literature and its offshoots have failed to offer a satisfying formulation of sophistication that has any normative value at the level of the individual citizen. Critiques of sophistication scholarship have in fact been exclusively concerned with the question of collective outcomes, in the process often depicting the mind of the average citizen as a *tabula rasa*, which responds mechanically to the signals of thought leaders. Whereas Converse argued that the distribution of sophistication was highly skewed, the new variable, political 'competence,' is depicted as having a flat distribution. The latter is an inevitable consequence of presenting purely stylized accounts of political behavior, whether heuristic-based decision-making (Lupia, 2006), or other social psychological accounts, such as online processing (Lodge et al., 1995, 1989). As such, it may be questioned whether critics of sophistication scholarship have offered any new variable worthy of study in its place. It is not clear, for example, who could actually be politically 'incompetent,' under the competence framework that has been proposed.

In addition, just as Converse failed to show what purpose his concept of sophistication serves, his critics have likewise failed to show the value of 'competence,' despite the more

pragmatist rhetoric. For example, the question of competence is couched in terms of making decisions that best serve one's 'interests,' but without tackling the issue of how one knows what these are. Indeed this is where the pragmatist emphasis on 'procedural knowledge,' in which political participation is perceived as analogous to riding a bicycle, shows its limits. One may ride a bicycle to get from A to B for some important purpose, or for no other reason than the fun of it. In either case, one is equally 'competent.'

Toward a New Conception of Political Sophistication

Given the persistence of the debate concerning the classic conception of political sophistication, one appealing idea might be to dispense with it entirely. One could, for example, simply substitute the more neutral concept, political 'knowledge,' and, to avoid being dogmatic, adopt the broadest possible definition. A problem remains however in that this approach would still not allow one to distinguish between the different purposes for which such knowledge can be used and, as such, would still fail to offer a normative conception of value to the citizen.

Rebuking the philosophical idealists of his day, Bertrand Russell argued that the field of logic should no more admit a unicorn than the field of zoology (Russell, 1993: 169), and went on to make the point that the use of abstractions is not license to depart from the real world. *A fortiori*, it might be said that a focus on the abstract and empirical in the field of political behavior should not be license to admit absurdities, such as a formulation of political sophistication which, as conceded by Luskin, has nothing to do with acuity, or a formulation of political competence which suggests one is liberated by political ignorance.

As such, one possible way forward is to take the normative question more seriously by making one's goals and values themselves constitutive of political sophistication. Sophistication then ceases to be a purely instrumental phenomenon, potentially serving destructive purposes. In turn it follows that, for sophistication to have normative appeal, such goals and values must be of a character that offers the possibility of consensus. The essence of what is intended here then by the term 'political sophistication' is captured in the following definition:

$$\text{Political sophistication} = \text{political knowledge} \times \text{values}$$

Again the analogy drawn earlier between Converse's study of political sophistication and Kenneth Arrow's study of social choice is revealing. Having demonstrated his impossibility theorem, Arrow went on to consider ways out of his logical cul-de-sac in which the aggregation of individual 'rational' preferences could not be guaranteed to yield a rational collective outcome. His musings led him to a possible distinction between one's overtly expressed preferences and one's ultimate values (the latter of which may never be fully formulated), or what he alternatively referred to as the distinction between 'social decisions' and 'social ends.' As Arrow observed, "The relation between the two sets of values is not unique; for a given set of ultimate values, there may be differing sets of instrumental values, depending on the greater or lesser knowledge of the individual as to the best means of achieving his ultimate values and as to what his ultimate values are" (Arrow, 1951: 86–87).

Bringing values and goals back into the framework as analytical constituents of political sophistication implies the rejection of Converse's classical formulation based on ideological constraint as well as the rival conceptions based on 'competence.' Both approaches have treated one's goals and values as exogenous and fixed, in turn depicting the role of the citizen as only choosing between predetermined options. In particular, those advocating the political competence framework have in turn ridiculed the classic notion of the informed, engaged citizen and argued that citizens are more 'free' to the extent their participation in the polity is minimal. Under this view the use of heuristics or proxies as a decision-making mechanism contributes to this freedom by allowing one to do 'more with less.'

Yet such a perspective overlooks a distinction made by Sen (1992) between 'well-being freedom' and 'agency freedom.' The latter concept is especially pertinent to politics:

> If a person aims at, say, the independence of her country, or the prosperity of her community, or some such general goal, her agency achievement would involve evaluation of states of affairs in light of those objects, and not merely in light of the extent to which those achievements would contribute to her own well-being.
>
> Sen, 1992: 56

This distinction is problematic for the concept of political 'competence' which pertains only to well-being achievement, while treating one's goals as if they can be objectively determined. Yet if such interests cannot be so determined, the competence criterion does not have any reference point. The concept of 'agency freedom' underlines the point that political freedom is not simply a matter of choosing between predetermined options but also pertains to the choice of which options are to be available to choose from. As such, the whole concept of political 'competence,' rather than increasing one's freedom, assumes away some of its important aspects.

"When the facts change, I change my mind" J.M. Keynes is said to have quipped in response to a critic, asking in turn "What do you do, sir?" The political sophisticate, according to the classic Conversian formulation, would presumably respond along the lines of: "Nothing, I think only in terms of abstract ideas," while the political 'competent' might similarly respond "Nothing," albeit with a different qualification: "Until I receive a signal to do otherwise." The first response conveys an inadequate conception of knowledge while the second indicates an absence of goals and values. Neither response seems worthy of the term 'sophisticated.'

In short, there seems no justification to promote the ideological constraint principle as the basis for political sophistication. Nor are the problems associated with Converse's classic formulation solved by changing the topic to 'competence.' The development of ones goals and values, the maintenance of a belief system that is not closed off from the factual world, and the adaptation of one's norms in light of changing circumstances and insights all seem relevant to what it must mean to

be politically 'sophisticated.' Further, it is contended here, the question of goals and values is every bit as relevant as the question of how much information one holds, the coherence of one's beliefs, or one's level of procedural competence.

The formulation of political sophistication offered here will be objectionable to those who insist that any formulation of political sophistication in the field of political behavior must be strictly empirical. This argument, however, is suspect on several counts. First, Converse's classic formulation of political sophistication was very quickly adopted as a normative ideal in the political science literature (Luskin, 1987). Likewise, the various accounts of voter choice and public opinion formation offered in reaction to it have invariably been justified on normative grounds (Lupia, 2006; Stimson, 2004; Lodge et al., 1989, 1995). Yet perhaps the best defense against this objection is to simply note the irony that political behaviorists, in their efforts to be strictly abstract and empirical, have adopted theories of knowledge, such as pragmatism and coherence theory, which relegate the whole importance of data and facts. Ignoring the normative question has turned out to be self-defeating and no satisfactory formulation of political sophistication seems possible without it.

Ideologies, Institutions, and the New Institutionalism

Dirk Sauerland, Witten/Herdecke University, Witten, Germany

Abstract

Within the last decades new institutionalisms have been developed in political science, sociology, and economics. The variety of analyses is large: In political science institutionalism a rational approach, a historical and a sociological can be distinguished. Sociology itself has developed a new institutionalism which is similar to the political sociological approach. Finally, New Institutional Economics has become a growing part of economic theory and empirical research. All these approaches have a strong focus on institutions, their logic, their origin, and change in common. However, a common definition of institutions is missing in all of approaches. The discussion in the new institutionalisms becomes even more complex, when the phenomenon 'ideology' is introduced into their analyses. The challenge then is twofold: Ideologies and institutions must be clearly distinguished if both should play a role in theory, and both have to be put to empirical testing, to prove their power in explaining real-world phenomena. Although the new institutionalism in social science are no longer new, there still has to be done a lot of work, especially to understand the logic, origin, and change of ideologies and their impact on the performance of political and economic systems and organizations.

New Institutionalism in Social Sciences

Although the insight that '*institutions matter*' is not new, it was neglected for a long time in social sciences. But during the last decades, it has become more popular again. Recently there are new approaches in sociology, political sciences, and economics with a clear focus on the influence that institutions have on human behavior, on their origin, their change, and their impact on the performance of different organizations, economies, and political systems.

The new institutionalisms have a common interest in institutions but their theoretical and empirical approaches are quite different because of their roots in different sciences. These roots also influence the research objectives: Whereas New Political Institutionalism (NPI) analyses the function and origin of institutions in the political sector, the focus of New Sociological Institutionalism (NSI) is more on the organizational level. New Institutional Economics (NIE) has developed different research areas which refer to organizations within the economy, to the economic system, and to the political system being both parts of the larger societal system. In all of these settings, the distinction between the activities framed by a given set of institutions (choice within rules) and the activities to design such institutions (choice among rules) is an important aspect of institutional analysis.

Over the past decades New Institutional Economics has become a growing and recognized part of economics. Leading scholars of NIE have been awarded with the Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel (colloquially the Nobel Prize in Economics), for example Elinor Ostrom and Oliver Williamson (in 2009), George A. Akerlof (in 2001), Douglass C. North (in 1993), Ronald H. Coase (in 1991), and James M. Buchanan (in 1986).

One characteristic of the new institutionalism in economics is its application of the general economic approach to human behavior. In contrast to traditional neoclassical microeconomics, the institutional microeconomic approach does not assume perfect information of all relevant actors. Instead imperfect or asymmetric information is a key assumption in the analysis of institutions.

A similar rational choice approach exists in New Political Institutionalism. However, there are two other branches that have been developed in NPI. Taking a different perspective than the rational NPI, the sociological NPI approach sees institutions not as a consciously chosen means to an end. Institutions are perceived as the result of a cultural development. Accordingly, this branch of political institutionalism has its focus more on the function of institutions than on their origin. The third political institutionalism is labeled as historical and combines parts of the rational and the sociological approach. Institutional development is always seen before a historical background, which is on the one hand culturally embedded but on the other hand also a rational decision of political actors within the given historical and sociological context.

Finally, there is also a NSI. A key element in NSI analyses is the diagnosis that not only institutions do influence individual's behavior. Social ties and relations in which individuals are embedded also have an impact on their behavior. In addition, the sociological institutionalists assume that the existing institutions influence the following changes of institutions by themselves. With this idea the sociological institutionalists argue similarly to the economic institutionalists, but put even more emphasis on the path dependency of institutional development and the persistence of institutions.

Institutions and Ideologies: The Logic of Institutionalisms Compared

For most of the interesting issues in political and economic markets, uncertainty, not risk, characterizes choice-making. Under conditions of uncertainty, individuals' interpretation of their environment will reflect their learning. Individuals with common cultural backgrounds and experiences will share reasonably convergent mental models, ideologies, and institutions; and individuals with different learning experiences (both cultural and environmental)

> will have different theories (models, ideologies) to interpret their environment.
>
> Denzau and North, 1994: p. 3f

This quotation refers to the question, why human beings adapt rules, develop routines, and act according to them in everyday decision. The answer is: to reduce uncertainty and the complexity of the individual decision making. Irrespective of being called institutions or ideologies, these phenomena provide helpful orientation for individuals. It is a major assumption that all new institutionalisms have in common: ideologies and institutions are influencing individuals' behavior.

The concepts of ideologies and institutions have at least one more thing in common: There is no standard definition of both. Not only the different disciplines in social science have different perceptions of both terms, also within political sciences, sociology, and economics different definitions of both terms exist. As a result of this variety of definitions, it is even difficult to distinguish between institutions and ideologies. The next section tries to clarify this definitional complexity.

Institutions in Social Science

Although there is no common definition of institutions in the social sciences literature, they are in general and broadly defined as 'the rules of the game.' Games – in this definition – are played by more than one person. They are collective undertakings in the political arena, in society, in organizations, or in the economy. Therefore, institutions are broadly defined as a set of rules that frame the interaction between members of different size collectives. However, the areas of application vary in the different new institutionalisms. And there are some specific aspects in the science-specific definitions.

Institutions in Political Science

With regard to the definition and analyses of institutions, two basic approaches exist in NPI. The first can be labeled as 'calculus approach,' the second as 'cultural approach' (cf Hall and Taylor, 1996: p. 7f).

The calculus approach in NPI assumes that individuals try to maximize the attainment of a defined set of goals. Being similar to the economic approach to human behavior, the NPI calculus approach has a clear microfoundation. Institutions in this respect may be defined as framing rules for the interaction of different individuals. They affect individuals' behavior and they are relevant because of the strategic interactions of those individuals in a given context. Institutions that are shared by a group of people reduce uncertainty about the potential activities of the group members. They are productive because they enable better reactions on others' actions.

In contrast to that, the cultural approach in NPI sees individuals more as satisficers than as maximizers. Individuals' behavior in this approach is not merely strategic but also influenced by their 'Weltanschauung.' Under this framework, individuals develop a set of behavior patterns to reach their goals set. Institutions in this respect serve as moral or cognitive templates for the interpretation of the world around. Defined in this way, institutions not only provide information for strategic behavior, but they affect individuals' identities and their preferences.

Apart from this broad definition based on functions, the three different institutionalisms in NPI have their own special focus on institutions and own specific definitions.

To start with, in *historical institutionalism* institutions are defined as "formal and informal procedures, routines, norms and conventions embedded in the organizational structure of the polity or political economy" (Hall and Taylor, 1996: p. 6). Historical institutionalists do obviously not only apply the calculus but also the cultural approach (especially when referring to the social embeddedness). In their concept of institutional analysis, historical institutionalists emphasize the asymmetrical distribution of powers resulting from the existing institutions. They also assume path dependencies in institutional development, therewith analyzing persisting institutional settings. Finally, historical NPI is open to incorporate other factors that influence political outcome in its analysis. Examples for such other factors are beliefs and ideologies.

In contrast to this flexible theoretical basis, *rational choice institutionalism* in political science adopts the calculus approach very strictly (cf Hall and Taylor, 1996: p. 10ff). Institutions are again seen as the rules of the political game. In this game they help to solve some problems of collective actions, such as unstable majorities. Institutions do that by lowering transaction costs and enabling gains from cooperation or exchange, respectively. Here the close relationship of rational choice NPI to New Institutional Economics becomes obvious.

Rational choice institutionalists assume – in line with the economic approach to human behavior – a given set of individuals' preferences. Individuals are assumed to maximize the attainment of their preferences. Scholars of the rational choice approach have also a focus on collective action dilemmas. Those can often be solved by adequately designed institutions. Those institutions frame strategic interaction of the individuals concerned.

Also the *sociological institutional* approach in political science has some distinctive features. Sociological institutionalists "tend to define institutions much more broadly than political scientists do to include, not just formal rules, procedures or norms, but the symbol systems, cognitive scripts, and moral templates that provide the 'framing of meaning' guiding human action" (Hall and Taylor, 1996: p. 14). Doing this, the concepts of institutions and culture become more similar than in the other NPI approaches. Some scholars even redefine culture itself as an (informal) institution.

In contrast to the rational choice institutionalists, which take the preferences of the individuals as given, the sociological institutionalists assume that institutions affect the underlying preferences or identities of the individuals by themselves. Consequently, individual choices are not only influenced by institutions but also by cultural specificities which result from the context-related embeddedness of the actors.

Institutions in Sociology

The New Sociological Institutionalism shows, not only by name, similarities to the sociological institutionalism in political science.

NSI has a clear focus on the institutions framing organizations and the analysis of their members' behavior. Institutions obviously matter, but what are the relevant institutions in this setting? Basically again institutions are defined as the rules of the game people play within organizations. Having a closer look at the formal organizational rules – for example, within a firm – the question comes up, why some people follow the rules and some not.

Avner Greif proposed a first answer to questions like these referring to the informal, i.e., not written rules. He argued that informal rules, beliefs, and norms combined with the set of formal rules motivate and guide behavior of individuals in organizations. Taking these informal rules into account, Greif (2006) analyzed in game theoretic models various principal agent relations within organizations. His approach fits well with the definition of institutions that Powell and DiMaggio (1991) suggested: institutions are rules, procedures, organizational standards, and governance structures plus conventions and customs. All of these factors define the actions of a rational actor.

Conventions and customs in this definition refer to another important factor influencing individuals' behavior. Mark Granovetter (1985) highlighted, that the impact of formal institutions on the behavior is often overestimated. Formal institutions, as mentioned before, reduce uncertainty by creating trust. Granovetter added that not only formal institutions create trust in an organization. Social ties and networks that exist within organizations have the same effect. These networks and ties are part of the organization but they are not formally fixed. However, the idea that members of an organization are embedded in such informal social structures was important for the development of NSI.

In addition, no single individual can control the effects of a networks; the social context is therewith beyond the individual's control. Having this in mind, the idea of maximizing individuals' goal attainment becomes obscure. In line with the arguments developed by Herbert Simon (1957) individuals being confronted with formal organizational rules and social embeddedness are facing highly complex decision situation. They cannot maximize their goal attainment but will probably 'just' satisfice their behavior. Again, adapting routines or stable patterns of behavior, respectively, makes their life easier.

Institutions in Economics

According to Douglas C. North, one of the most prominent scholars in New Institutional Economics, institutions are "humanly devised constraints that structure political, economic and social interactions" (North, 1991a: p. 97) or, in short again, 'the rules of the game.' The explicit reference to political and social interactions indicates that NIE analyses are not restricted to the core economic sphere. As NIE analyses the institutions of the economic system, within organizations and in the political sector, its range of application is very broad and gives room for economic imperialism, i.e., competitive analyses of NIE in the typical application fields of NPI and NSI.

From the NIE point of view, institutions that are accepted by the participating players enable productive cooperation. They reduce transaction costs for rational decision makers in various contexts and therewith provide the framework to generate mutual gains from cooperation. This perception is obviously very similar to that of the rational approach in NPI.

Having a closer look at the meaning of institutions and their field of application the New Institutional Economics distinguishes different kind of institutions. First, NIE analyses distinguish between formal and informal institutions. Second, there is a difference between internal and external institutions. Third, we find the distinction between institutions and ideologies, both defined to be shared mental models of different individuals (Denzau and North, 1994).

As mentioned in the earlier quotation by North, NIE analyses a wide range of institutions under different foci. One focus is the general role that institutions play within the economic approach to human behavior. In addition to this positive part of institutional theory, the normative question in institutional design is a major part of ongoing research. The focus in this normative part of NIE lies on the choice among rules. The research question is: how should institutions be designed to generate a certain behavior of the actors subject to that rules?

"The rational choice framework assumes that individuals know what is in their self-interest and make choices accordingly. […] Instead people act in part upon the basis of myths, dogmas, ideologies and 'half-baked' theories. Ideas matter; and the way that ideas are communicated among people is crucial to theories that will enable us to deal with strong uncertainty problems at the individual level." This quotation from the seminal paper *Ideologies and Institutions* by Arthur T. Denzau and Douglass C. North (1994) provides a good insight into the concept of institutions and ideologies. Both phenomena are, in the positive theory, tools to cope with uncertainty, which is – more or less – the omnipresent context for decision making in reality. Under uncertainty rational decision making is more than difficult. And individuals – as Denzau and North point out – are aware of the difficulties they are facing.

To begin with the individual's level, internal institutions are those rules that individuals adapt to restrict voluntarily their own set of decision options. This kind of self-restriction is useful to reduce uncertainty within repeated and similar decisions situations. If decisions taken proved to be successful, rational decision makers will remember in similar situations these beneficial strategies and will react (if not identically) in a similar way. In contrast to that, decisions that resulted in a low utility level will (probably) not be repeated. To reduce their decision problems under uncertainty individuals learn and adapt. Thus, individual learning results in the set of behavioral patterns that will be applied regularly. A prominent example in world literature for an internal self-restricting rule is Ulysses' reaction to the challenge of the sirens (cf Elster, 2000).

Whereas internal institutions are applied on the individual action level external institutions frame the interaction of groups of people. Formal external institutions are typically fixed and transferred in a written format. Prominent examples are constitutions, other legal rules, and private contracts. In contrast to these written format rules, informal institutions do also shape the behavior of the collectives' members, but are not fixed in a written way. Culture is – in NIE – one prominent example for informal rules: it clearly has an impact on the individual's behavior in a larger group of people (as societies in general) and also in smaller groups (e.g., a company). However, it is just orally transmitted for example by education.

As a result, individuals are embedded (in the logic of Granovetter) in informal cultural ties. The logic of formal and informal institutions is that they influence individual's behavior and therewith limit the available set of actions to be chosen from.

Informal institutions are sometimes transferred into formal institutions, especially when group size increases. Examples for this development are the modern, formally fixed corporate governance codices that substitute the traditional informal rules of decent behavior in business activities.

External institutions, either formal or informal, are not per se stable. Mechanisms to sanction an inadequate behavior therefore play an important role. Here not only the value of the penalty is relevant but also the probability to be detected as a rule breaker.

Institutions in this sense are shared by different people. Denzau and North (1994) therefore define institutions as some 'shared mental models.' A mental model is an internal institution that helps the individual to understand the world. It provides a structure to interpret the social and economic interactions. If some people develop similar interpretation structures, they share these mental models. This again helps to develop informal and formal institutions that then structure the social and economic activities, according to those shared mental models. In fact, institutions that shape the behavior in a group of people are an expression of their shared models.

Ideologies in Social Sciences

One of the best known definitions of ideologies in social sciences is that of Karl Marx. He referred to ideologies as a quality of thoughts, especially in the social context, that is illusionary or distorted. Apart from the idea of ideologies as mental misconception of reality and the relationships of individuals to their social surroundings there are more topical conceptions of the term ideology within the discussion about new institutionalisms. And most have one perception in common: ideologies are shared by a group of people, often having similar goals in politics, or in other of different size collectives. In terms of Denzau and North (1994) an ideology is another category of shared mental models.

Ideologies in Political Science

If institutions and ideologies have some similarities and differences, theoretical and empirical analyses become complicated. With this regard Mullins (1972) made a helpful contribution to the discussion 'on the concept of ideology in political sciences' with two statements: First, there must be an accepted definition of the term to distinguish it from other similar (social) phenomena. Second, it is necessary to conceptualize ideologies in order to make it an empirically relevant term. Whereas the first aspect refers directly to the discussion about ideologies and institutions, the latter is a more methodological aspect about empirical relevance as a measure of the quality of theories developed. To define ideology – in distinction to other similar phenomena – Mullins presented four arguments.

The first argument refers to ideology as an indicator for historical consciousness. Ideologies provide the cognitive power to identify recurrent aspects of experiences from the past in applying both, abstraction and generalization. It therewith provides, on a positive theory level, an interpretation scheme of the reality based on learning from history.

The second argument is that ideologies provide structured conceptions of the driving forces within the social world. Doing this, ideologies serve simultaneously as benchmarks for the evaluation of real-world policy making. This has a clear normative aspect.

The third argument develops the evaluation idea further. If, for example, the real-world policies are not according to what the prevailing ideology suggests, evaluations typically result in activities of political change. Ideologies are therefore a major source for political reform acts. These reforms can also address the institutional design. If the existing design is not compatible with the majorities' ideology, the institutions will be changed and become adapted to prevailing ideology. Ideologies define – in their normative tenor – objectives to be aimed. Ideologies also foster communication among group members about evaluation, ideals, and purposes. In doing this, ideologies help to mobilize group members, especially if a certain objective seems to be missed by status quo politics.

The fourth argument refers to logical coherence. This coherence, according to Mullins, distinguishes ideology from mere ideas, attitudes, or feelings about politics. However, the logic of an ideology can be broadly defined. As emphasized also by representatives of NSI and NIE, an ideology must make sense. Logical inconsistencies make ideologies vulnerable to upcoming new competing ideologies. And there are most likely more inconsistencies to be found the more mature and sophisticated an ideology becomes.

Going further in time, the term ideology is nowadays used more sophisticatedly, referring to different groups within society. Analyzing *Ideology and Institutions in North America*, Finbow (1993) distinguishes, for example, two basic kinds of ideologies. Organic (or inherent) ideologies arise from social relations and economic conditions, whereas traditional (or derived) ideologies are more formal propositions drawn from traditions and history. In this strand of literature, institutions and ideologies are interdependent variables: ideologies do not only influence the character of policy and institutions, they interact with institutions and social conditions.

In Finbow's definition, formal, society-related ideologies are beliefs and/or values that are often derived from major events in a nation's history. They provide context for a later evolution of ideologies and institutions and they shape the initial policies, parties, and institutions. Such major events can be, e.g., (civil) wars; such events are deeply rooted in the shared memory of a society.

In contrast to these national ideologies, organic ideologies are group related and developed by social groups in response to their specific circumstances and interests. Looking at the organic ideologies, Finbow differentiates further between popular, central, and public ideologies. These relate to different smaller groups within society, each – more or less – trying to reach its own goals. This argument is similar to that developed by Mancur Olson (1965) in his *Logic of Collective Action*. Following this logic, popular ideologies are based on the experiences of popular groups within a society. These groups, like political parties, have influence on public policy-making by electoral power or other channels. The idea

of a central ideology refers to the economic system as a whole. Central ideologies are created and driven by business and professional groups; they are bound to self-interest or social awareness. This kind of ideology can be the underlying idea of an economic order like the Social Market Economy in Germany.

Finally, the public ideology refers to state actors and linkage agents. They are based on traditional beliefs, for example, about the role of the administration in government, group pressures, such as lobbying activities, or other agency interests.

Ideologies in Sociology

As with NPI and NIE ideologies are far less in the focus of analyses of sociological institutionalism than are institutions. In fact, they have been widely neglected for a long time. But in 2009 some sociologist published a volume of works on *Institutions and Ideology*. One of its purposes was "to encourage re-engagement with the notion of ideology in contemporary institutional research" (Meyer et al., 2009: p. 9). The editors justify their attempt to do this based on the insight that "the silence with regard to ideology is surprising since many of the core concepts of institutional theory, such as institution, legitimation, social categories, institutional logics, and theorization, are, in one way or another, closely related to the notion of ideology" (Meyer et al., 2009: p. 2).

This statement implies – again – that ideologies and institutions are in a close relationship. Institutions shape the individual's behavior and social context. They form social entities, which are the basis for any social order. Ideologies are important for institutional design because institutions incorporate the underlying ideology that is shared by the members of a social entity. Ideologies then have a twofold impact: they legitimate a certain social order and they constitute that order in the first place.

Going back in history, Karl Marx' conception of ideology also plays an important role in sociology (cf Marx and Engels, 1990). A second prominent scholar in sociological research on ideology was Karl Mannheim (1972). He saw ideology more as a general phenomenon, claiming that all human perception of reality is influenced by the socio-historical circumstances. Human thoughts are therewith context related and always influenced by ideologies (as the before mentioned 'Weltanschauung'). Ideology is then a system of beliefs shared by a group of individuals. Following this tradition, Simons and Ingram (1997: p. 784) define ideologies as "a set of beliefs about how the world operates, including ideas about what outcomes are desirable and how they can best be achieved." In this definition, ideologies have again a positive and a normative aspect.

Of course, NSI also has to solve the problem of distinguishing ideologies from institutions. As there is no common definition of both terms, there are different suggestions for distinction.

Some scholars argue that ideology is the link between the framing institutions and individuals' behavior. Following this logic, differences in the underlying ideology that individuals share can help to explain differences in individual behavior under a given set of institutions. Accordingly, Vogel (2009: p. 93) in the volume mentioned defines ideology as "a system of beliefs shared by a particular social group for whose members it has immediate behavioral implications." Vogel also defines four essential features of such an ideology.

First, ideologies are a cognitive framework that helps to understand (positive aspect) and to 'design' the world (normative aspect). In addition – like in the political sciences – ideologies have a certain systematic structure to interconnect the different parts of belief elements. This is similar to the idea of ideologies being logical structures, which we discussed in the previous paragraph. Ideologies, according to Vogel, also create group consciousness by formulating consensual positions of the different group members. Finally, ideologies themselves influence individuals' behavior providing legitimization for certain behavior or nonbehavior.

Taking this focus, ideologies are complementary to the formal set of institutions. They form the nonobservable part of the institutional system and, at the same time, are the starting point of institutions origin and change.

Looking at the logic of ideologies in New Institutional Economics, similar ideas can be found.

Ideologies in Economics

As institutions, the ideology people share has an influence on their behavior. Compared to informal and formal institutions, ideologies are not the rules of the game but – in a positive theory – the 'ideas of the game.' And ideologies can also be ideas about how the game should be structured (normative approach). Denzau and North (1994: p. 20) define both, ideologies and institutions, as different classes of shared mental models: "Mental models are shared by communication, and communication allows the creation of ideology and institutions in a co-evolutionary process."

An ideology provides a positive mental model that is – according to Denzau and North – focused on action and valued outcome. In this respect, an ideology enables people in a society (or other collectives) to choose compatible behavior patterns. It defines a set of possible actions with which an individual can reach his or her utility driven aim best. From a normative point of view, ideologies provide a pre-selection of possible actions. They "identify the aspects of reality that are crucial for achieving one's goals" (Denzau and North, 1994: p. 15).

Ideologies and Institutions: Differences and Similarities in Concepts

Until today there is no generally accepted definition of the terms institution and ideology in social sciences. There is also no accepted approach to distinguish both phenomena. And there are a lot of other phenomena and terms, that are also present within the discussion about ideologies and institutions. **Figure 1** summarizes the phenomena discussed earlier and highlights some of their relevant interrelations.

Apart from the differences in NPI, NSI, and NIE, there seem to be some core elements (almost) all institutionalism have in common.

1. All institutionalisms see institutions and ideologies generally as means oriented.
2. All share the idea that institutions and ideologies help to structure human interaction, therewith reducing complexity.

Figure 1 Institutions, ideologies, and embeddedness – an overview.

3. Ideologies and institutions – shared by a group of people – create trust among the group members; but they are not the only sources for creating trust.
4. Both help to make the reactions of the other group members better foreseeable, therewith reducing uncertainty.
5. Especially the institutions assign responsibilities – in the relevant political, organization, or economic context – and therewith allocate power.
6. Prevailing ideologies are an underlying logical structure for the set of institutions shared by a group of people; institutions and ideologies are interdependent.

Vogel (2009: p. 94) underlines the last aspect: "Ideologies are the non-observable and ideal part of an institutional order that is, and must be, related to material practices."

Looking at the three new institutionalisms in social science, the major differences between them result from the methodology they apply. Some approaches clearly apply a rational choice approach: this is very prominent in NIE, but also in parts of the NPI and NSI. On the other hand, the cultural approach is fundamental for most NSI approaches, but makes also its way into some NPI and NIE approaches.

This basic difference in the perception of institutions (and ideologies) has an important impact on the way institutional and ideological origin and change is analyzed. Facing competing explanations of institutional impact on individual behavior, empirical testing of the concepts may be helpful to distinguish the relevance of explanations.

Unfortunately, one of the major challenges for all three institutionalisms still is to conceptualize ideologies and to have, for example, a precise distinction between ideologies and informal institutions. If there is no clear definition of both terms and if ideologies are, as the quotation earlier indicates, the nonobservable part of institutional systems the empirical testing of both concepts faces serious challenges. However, there are empirical analyses on the impact of ideologies. We mention some in Section Ideologies and Institutions: Empirical Relevance.

Ideologies and Institutions: Origin and Change

Apart from the mere logic that institutions and ideologies help to reduce uncertainty in social, political, and economic interactions and relationships two other major questions in social science are about the origin and change of both, institutions and ideologies.

Generally speaking, there are two different perceptions of the origin of ideologies and institutions in new institutionalism literature. The first is to see both social phenomena evolving in an evolutionary process, sometimes as the unintended collective consequences of activities based on individuals' intentions. This perspective is typically assumed by the proponents of the more cultural approach on ideologies and institutions. Accordingly, the researchers applying a rational choice approach typically have a different focus. They assume especially institutions to originate as a result of rational decisions, either of the people affected, e.g., in democratic processes, or of owners and managers, e.g., in hierarchical structures.

In addition, some institutionalisms have a focus on the origin and change of institutions, others take them as somehow given and just analyze the effects of the given set of institutions and its change.

Ideologies and Institutions: Origin

To give a short survey about the different foci and perceptions, we start with the NPI approaches. *Rational choice NPI* has a focus on the origin of institutions. In this strand of literature, institutions originate on purpose because of the function they have to fulfill in the political arena. Consequently, institutional change is also modeled as a conscious choice among rules (Hall and Taylor, 1996: p. 19f). Change will be initiated by the relevant actors if the costs of change are lower than its benefits, which again refer to the purpose of the institutions. *Historical and sociological NPI* both have no focus on the origin of institutions but assume that an initial set of institutions is given before new institutions are adapted or created (Hall and Taylor, 1996: p. 20ff). Taking the perspective of *sociological NPI*

these initial institutions shape the origin of new institutions, because they influence the mental models of the institutional entrepreneurs. The origin of institutions in this perspective is not just means-end related but is the results of interactive processes between the collective members. By communicating with each other the individuals develop similar ideas about how the social world works and how institutions could be designed to structure the social world adequately. *Historical NPI* often focuses on the distribution of powers resulting from the initial set of institutions. This distribution determines the ability to create new institutions in the course of time.

The *NSI perspective* on the origin of institutions is, not surprisingly, similar to that of sociological NPI and also applies a more cultural than a rational choice approach.

Finally, in Denzau and North's *NIE concept*, ideologies help individuals to build a mental model and develop a set of internal institutions. Because ideologies are a 'blueprint' for building these models, individuals that use a preformed ideology are able to develop a mental model faster than those who rely on their own experiences, built on individual-learning processes. However, these individual-learning processes in both cases have an impact on internal institutions, mental models, ideologies, and external institutions.

The Evolutionary Approach: On Ideologies and Institutions

To see how communication and interaction between members of a collective can lead to the evolutionary origin of ideologies and institutions, we will briefly sketch the logic of an NIE approach in this paragraph. To explain that logic, we refer to a statement by North (1993: p. 20): "Formal rules are an important part of the institutional framework but only a part. To work effectively they must be complemented by informal constraints (conventions, norms of behavior) that supplement them and reduce enforcement costs. If the formal rules and informal constraints are inconsistent with each other the resulting tension is going to induce political instability. But we know very little about how informal norms evolve."

Decision making under uncertainty is omnipresent, for political as much as for economic decision makers. Only very rarely the outcome of a decision in a social context is certain. Learning means, as mentioned earlier, dealing with complexity and uncertainty. If individuals realize that a decision was for their benefit, this pattern will become part of their typical behavior. Decisions with a nonsatisficing impact on their target will not be repeated. The learning process results in a set of successful behavioral patterns that serve as internal rules for decision. These *internal rules* or routines, respectively, reduce uncertainty and – in terms of transaction cost economics – and therewith reduce the costs of decision making. As an individual's mental model, they provide orientation in a complex environment. From a rational choice perspective, individuals will stick to their internal rules or institutions if the benefits of a restricted set of alternatives are assumed to be higher than the costs of making wrong (or utility decreasing) decisions (Heiner, 1983).

Having a look at **Figure 1**, the individual mental models become shared mental models via communication. In other words, communication is the basis for the evolutionary origin of *ideologies*. The process of ideology origin may be accelerated by ideological entrepreneurs, taking a leadership role in ideology development. As Denzau and North (1994) pointed out, ideologies and institutions evolve in a co-evolutionary process.

If the decision making of an individual shows regularities the individual's behavior becomes predictable for other individuals who interact with him or her. If, for example, a businessman (-woman) is known to be fair-minded, this is beneficial for all his or her cooperation partners. Build upon reciprocity, to stick to the rule of 'be fair-minded' creates trust in each other's behavior and therewith produces benefits for the group of interacting business people. Adopting and sharing this *informal external rule* in a group enhances the predictability of individual behavior and lowers transaction costs. More gains from cooperation can be realized. Adequately designed institutions, evolving out of an evolutionary learning process (Mantzavinos et al., 2004), are therewith productive.

However, informal external rules are, as mentioned earlier, not per se stable. Taking the game theoretical construction of the prisoners' dilemma as an example, the noncooperative position of the rule breaker can become a beneficial option for one of the group members. To prevent this, sanction mechanisms have to be implemented. In smaller groups these are typically social sanctions like exclusion from the relevant group.

As groups get larger, things become more complicated: rule breakers can no longer be easily detected and the costs for the others to find the rule breakers are high compared to the costs and individual rule breaker causes. Again, the members of the collective are facing the prisoners' dilemma situation. As a result, individuals could choose to set up *formal rules* and to have them stabilized by explicit sanction mechanisms (cf North and Weingast, 1989). At this time, the origin of institutions is no longer merely evolutionary. It becomes an act of rational decision making to ensure mutual gains from cooperation.

The Rational Choice Approach: On Institutions

The second way to think about the origin of institutions is therefore grounded in the rational choice tradition, which we find in political science and especially in NIE.

If institutions are means to solve collective (decision) problems, rational decision makers will search for adequately designed institutions to solve the relevant problems. In the NIE literature, there are examples of this theoretical approach for three different institutional settings: The formal rules framing the democratic system of a state are in the focus of Constitutional Economics. On the level of the rules for the economy as a whole, the German Ordnungstheorie provides an example for some conscious design of institutions. Finally, Transaction Cost Economics provides arguments for a rational design of rules, or institutions, respectively, on the organizational level.

Constitutional Economics, as a prominent part of NIE, models the foundation of a protective and productive state as a conscious and rational decision of all people affected (Buchanan, 1975). The logic of the argument starts again with a dilemma structure. It is the problem to find stable forms of living together peacefully in a larger group of people – the society. From the economics perspective, such a peaceful society is productive: trust is built and gains from cooperation can be realized. The rules framing this cooperative game therewith provide benefits for all people

accepting them. To overcome the free rider problems caused by potential rule breakers, there needs to be a new player in the game that monitors the rule acceptance and puts up sanctions for a breaking of the rules. This is, in short, the logic of a protective state.

The protective state ensures the property rights in a society and is founded in a social contract. This contract contains the rules of the game that all people affected can accept. Similar to Rawls' (1971) *Theory of Justice*, consensus on the rules is reached under a veil of ignorance. This construct helps to find acceptable rules for every member of the community because it prevents the citizens to pursue their individual interest in choosing the basic rules for the society. So, the theoretical model of Constitutional Economics is a rational choice among rules for the constitution of a state, but it is a choice under uncertainty. Built on this protective state, the next step – in theory – is the productive state. This is also framed, or constituted, by a set of formal rules that ensure, e.g., the provision of public goods and services by the state. In Constitutional Economics theory, the underlying ideology is not a central theme; the theory is just about the setting up of institutions.

But there are not just theories of conscious decisions about an adequate constitutional design. A prominent example for a real live experiment for the choice among rules-situation is the German Ordnungstheorie and their transformation into practical politics. This institutional approach, was established in the 1930s in south-west Germany. A team of economists and law scholars also known as the Freiburg School in a joint work developed a framework for a post-war economic constitution (Eucken, 1952) that later became the basis for the so-called 'Social Market Economy' in Germany. The ultimate goal of the theoretical and practical undertaking was to develop a framework for a workable and humane economic order ('funktionsfähige und menschenwürdige' Wirtschaftsordnung, Eucken, 1952: p. 14).

In a historical perspective, the institutional design developed by the scholars of the Freiburg School was affected by the shared ideology of those economists and jurists and the corresponding ideology of the political leaders in the post-war Germany. This ideology was a result of the experiences shared by exponents of the Ordnungstheorie. Based on their experiences with a totalitarian regime and the economic events before the war a 'social-liberal' ideology evolved. This started – in Finbows terminology (cf Section Ideologies in Political Science) – as a popular and public ideology of the people in academia and politics and then became a formal, society-related ideology for post-war Germany.

Two central ideas formed that social-liberal ideology: first, to ensure individual freedom (protective state) and second, to provide protection mechanisms against economic risk associated with unemployment, illness, and age (productive state). Built on this ideology, the scholars in Freiburg developed a set of rules that should be applied by the state to create a humane and workable economic order for the benefit of all people in Germany. These rules were designed to ensure a market economy shaped by workable competition processes in the first place ('konstituierende Prinzipien'). Those rules should be complemented by social security systems to correct for unintended effects of those competitive processes ('regulierende Prinzipien'). The security systems were meant to support the workability of the market economy. Correspondingly, the set of principles framing this order were labeled as constitutive and regulating.

The idea behind this institutional design is simple: The government should set the rules of the game called 'market economy' (choice among rules), whereas the private businesses and households should choose their best available moves within the given set of rules. The logic is similar to that of Constitutional Economics: if the government sets those rules and supervises their fulfillment, the outcome of the social market economy will be in favor of all citizens.

In the German Ordnungstheorie also the idea of a wide acceptance of the rules is a prominent one. In contrast to Constitutional Economics' theory, which assumes an explicit consensus about the founding rules, German Ordnungstheorie assumes a more implicit but broad approval as an indicator for the quality of the rules proposed.

The idea of a consensus or wide acceptance about the institutions is typical for a collective that is organized in a democratic way, i.e., providing participating rights for all members (Sauerland, 2013). This mode of legitimacy is different in hierarchical systems, like firms. Here Transaction Cost Economics (TCE), another important part of NIE theory, has its roots.

The design of institutions in organizations is perceived to be a rational choice, too. As owners and managers have clear ideas of the goal that 'their' organization has to fulfill, institutions in organizations are designed as a means to an end. From the TCE perspective, institutions are therefore designed to be efficient, with reference to the goals to be achieved.

One of the main research questions in TCE is to find the best organizational structure for different kind of transactions. In the governance approach, initiated by Oliver Williamson (1975, 1985), specificity of investment plays an important role when deciding which organization structure to choose for a transaction. Based on TCE arguments, markets (as institutions) are a very efficient organizational structure when generic transactions have to be performed. In contrast to that, a vertical integration is, ceteris paribus, the best organizational structure if highly specific transactions are involved. In this situation, the investor is facing the risk of being exploited by his cooperating partner when using markets to coordinate economic activities. The 'value at risk' in a hold-up situation involving market coordination is the so-called quasi rent. This is the difference in returns on investment in the first best utilization compared to the second best.

To ensure specific transactions from being exploited, institutional precautions are implemented – as a rational choice decision of the people affected. These institutions, e.g., explicit formal contracts, create trust. Investor and partner benefit from this institutional safeguarding because they can realize mutual gains from cooperation.

As in Constitutional Economics, ideologies do not play any explicit role in the TCE line of arguments. Individuals' behavior is framed by (formal) institutions alone, or as Granovetter (1985: p. 489) puts it, the mere focus on formal institutions suggests 'a conception of action and decision carried out by atomized actors.' It is this atomized actor that Granovetter refers to when he emphasizes the relevance of social embeddedness, thus making a point against this mere 'efficiency of

institutions' view. Granovetter (1985: p. 49) emphasizes this point: "Williamson vastly overestimates the efficacy of hierarchical power ('fiat,' in his terminology) within organizations."

Sociological institutionalists in the Granovetter tradition stress the point that not only hierarchical formal and informal structures frame the behavior of people working in an organization and therewith influencing the organization's performance. They point out the relevance of social networks and relations within an organization (cf Section Institutions in Sociology). As people working in organizations are embedded in various social relationships these also have an impact on their behavior. Social relationships and networks are also creating trust and they can also reduce transaction costs. But they are not necessarily created as rational decisions of utility maximizing actors. As discussed in the previous section, the origin of social ties is often evolutionary, the ties being an unintended result of other intended actions. From the trust-building and transaction cost-reducing perspective hierarchical structures and social embeddedness have similar effects. Not surprisingly Williamson (1994: p. 85) admitted: "Transaction cost economics and embeddedness reasoning are evidently complementary in many respects."

Similar to the two examples before, the institutions in the TCE line of arguments originate because of conscious decisions, not just evolutionary. Differently from democratic settings, in this organizational 'choice among rules,' a broad participation (bottom–up) in the decision-making process is not necessary. The institutions in organizations are typically chosen in a hierarchical top–down approach. However, the acceptance of the rules is also relevant for the success of the institutions in this case. If formal institutions are not accepted, they will neither reduce uncertainty nor create trust. They will also not provide a positive contribution in terms of economic success of the organization. Disapproved institutions will not reduce transaction costs and they will not be stable over a longer period of time. Nonacceptance is therefore a source of institutional change.

Except for the differences in the details describing the origin of institutions in the rational choice perspective, another important distinction between constitutional economics and the other theories mentioned refers to the rule setters. As similar the logic of political institutions and economic institutions on the societal level may seem to be, the challenges for the rule setters are completely different. Rules or institutions, respectively, are set for the economy by political decision makers. The actors in the economy have to adapt those rules. Obviously rule setters and potential rule followers are not identical.

Looking at the political institutions (and the institutions framing economic transactions in or between organizations) this is different. In the post-constitutional perspective changes in the constitutions have to be made by the same political decision makers that then have to play according to the new rules. With this perspective, political rules are more like internal rules. Although they are formally fixed, they follow the logic of self-restrictions. This may be one reason why constitutional changes are not often seen in reality, at least in a 'normal mode' of political activity.

Changes in the rules of the political game are more often seen in times of exogenous shocks in the society or in the economy. Crises are often a time for change even on the constitutional level (Acemoglu and Robinson, 2012).

Ideologies and Institutions: Stability and Change

Analyses of institutional change typically refer to changes in the general constitution and/or in the constitution of the economic system. In terms of Acemoglu and Robinson (2012) the specific political and economic institutions are responsible for the economic development and wealth in a certain country. Correspondingly, institutional changes can have a positive or a negative effect on both factors. Theories about institutional change typically distinguish between slow and disruptive changes. Causes for both can be either exogenous or endogenous. A disruptive change in institutions may be caused by endogenous ideological shifts. The corresponding line of arguments runs as follows:

Assumed there is a stable set of political and economic institutions in a country. This situation can be labeled, in terms of NIE, as an institutional equilibrium. Characteristic for such equilibrium is the compatibility between formal and informal rules and the underlying, dominating formal ideology. If these institutions exist for a longer period of time, the structure will result in a self-enforcing stable situation.

Individual actors in the political sector and in the economy will be able to better adapt their behavior to the existing set of rules. They will gain experiences in the handling of the institutions; uncertainty with regard to the logic and application of the institutional structure decreases. In this situation, the existing institutional structure becomes more productive over time, reducing uncertainty in interactions and therewith reducing transaction costs. From an NIE perspective, individuals learn to use the institutions properly; they invest in learning and in building up of successful patterns of behavior.

This process results in a path dependency of the institutional system. The institutions are stable and change is not very attractive for those who have invested in the knowledge of the system. The idea of a path dependency in the institutional structure is not only prominent in NIE analyses (esp. in the work of North) but also in NPI, especially in the historical and the rational approach.

However, institutional changes happen in reality. North argues that institutions' change is caused by a change in relative prices. These changes can be exogenous, caused by, e.g., wars or other catastrophic events for a country. A change in the price structure can also be endogenously caused, e.g., by major technical or organizational innovations.

Changes in relative prices mean a disruption in equilibrium. New technologies disturb the initial equilibrium between the private rate of return and the societal rate of return, which a set of political and economic institutions produces. In the light of the innovation, the private rate of return could be higher now whereas societal rate of return remains stable. In other words, the existing institutional structure limits the benefits for some (innovative) actors. Benefits would be higher if institutions were adapted to the new technological situation. As a result, those who would benefit more have strong incentives to try and change the economic (and sometimes also the political) institutions. In democracies there are established procedures to

enable and manage such institutional changes in the rules of the economic system in a peaceful way.

Based on the argument sketched at the beginning of this section, the new formal institutions must be complementary to the existing informal institutions and the dominating formal ideology. Those represent the guidelines for a successful slow change of the set of formal (economic) institutions (North, 1991b). In contrast to that, disruptive changes are typically caused by exogenous shocks such as wars or the sudden clearance of backlogs of overdue reforms.

A basic prerequisite for a peaceful and successful change in economic institutions are stable workable political institutions. Those ensure conscious negotiations on the political level about changes in the economic constitution. This logic highlights again the importance of a workable democratic system, which is typically characterized by adequately designed political rules to manage (not only institutional) change processes. A lack of workable institutions for political negotiations often results in a reform backlog. In this setting, necessary adaptions of institutions in the light of technological innovations are not going to happen. This may result in a blockade of necessary reforms. The only way to overcome such a blockage is a revolution and therewith a disruptive change in political and economic institutions.

Acemoglu and Robinson (2012: p. 96ff) take up this argument and look for critical junctures in history, where political institutions and economic institutions are not compatible, become unstable, and are changed. Their argument runs as follows: political and economic institutions can be extractive or inclusive. They are distinguished by the allocation of powers that result from those institutions. According to Acemoglu and Robinson (2012: p. 80), extractive institutions allocate the power in politics and economy to a small group of people: "If the distribution of power is narrow and unconstrained, then the political institutions are absolutist, as exemplified by the absolutist monarchies reigning throughout the world during much of history." Inclusive institutions, in contrast, spread the powers broadly and thus enable broad participation in political and economic decisions: "Inclusive economic institutions, […], are those that allow and encourage participation by the great mass of people in economic activities that make best use of their talents and skills and that enable individuals to make the choices they wish." (Acemoglu and Robinson, 2012: p. 74).

Complementary political and economic institutions develop their full potential of productivity if both are inclusive. A combination of extractive and inclusive institutions is generally assumed to be unstable. In this perspective, a lack of compatibility results in instability and change. Change, which is often a disruptive change, is triggered by critical junctures in history and depends on the pre-existing institutions: "The outcomes of the events during critical junctures are shaped by the weight of history, as existing economic and political institutions shape the balance of power and delineate what is politically feasible. The outcome, however, is not historically predetermined but contingent. The exact path of institutional development during these periods depends on which one of the opposing forces will succeed, which groups will be able to form effective coalitions, and which leaders will be able to structure events to their advantage" (Acemoglu and Robinson, 2012: p. 110).

This perspective combines a historical embeddedness of institutional change with an idea of path dependencies and political powers; in other words: it is a combination of a historical NPI- and an NIE-perspective. Apart from that, there is another interesting aspect in Acemoglus and Robinsons book in the context of this article: the term ideology does not play any role in their argument. This is different in some other approaches, for example in NSI (e.g., Vogel, 2009) and also in NIE (e.g., Denzau and North, 1994).

In these lines of arguments ideologies can be a trigger of institutional change: if ideologies change, this can result in an adaptation of institutions to the new majority ideology. Now what may be reasons for a change in ideologies?

Ideologies develop over time. After their origination they get adapted to the reality and to changes in reality. The older an ideology is, the more elaborated it will become. Elaboration means that ideologies become more sophisticated; they are adjusted, for example, if some logical inconsistencies are detected by followers of or opponents to an ideology. Denzau and North as Vogel suggest that a more sophisticated ideology becomes more vulnerable to criticism. This relates to the complexity of an established ideology: The more complex it is, the more likely will inconsistencies be detected, putting the established ideology under pressure. In this logic, the success of an ideology is at the same time its greatest risk.

Both, Denzau and North as Vogel refer to an analogy of this process to Kuhn's idea of shifts in paradigms in sciences. Taking this argument, shifts in ideologies are a result of logical incoherence. Ideological entrepreneurs (Denzau and North, 1994: p. 26) use these incoherencies and develop new, less sophisticated but more consistent competing ideologies. If ideological entrepreneurs are successful, because of support by the media or other opinion leaders, they can cause a shift in ideologies. And as ideologies are the underlying structure of the institutions of a society, the disruptive ideological shift means a crisis for the existing intuitions and therewith triggers institutional change, too. As Vogel (2009: p. 108) puts it: "[…] the failure of ideologically legitimate practices – after a certain point in time – becomes more likely with progressing institutionalization. Put simply, ideologies have an expiration date."

Ideologies and Institutions: Empirical Relevance

When it comes to the discussion about ideologies and institutions in new institutionalism, it is not only a question of theoretical reasoning. As mentioned in Section Ideologies in Social Sciences theories about ideologies and institutions must not only clearly distinguish between both phenomena but also have to put their logics to empirical testing. However difficult it is to model both phenomena properly in empirical analysis, testing is necessary to see a real-world impact of ideologies and institutions.

Since the beginning of new institutionalisms a lot of empirical work has been performed. There are not only qualitative analyses, like case studies but also quantitative, e.g., cross-country comparisons. For example, there is a growing literature in NIE on the impact of economic institutions that ensure freedom to choose within the economic system and also

in the political system. These studies often show that the degree of freedom provided by a set of institutions has a positive effect on the economic development and wealth of nations. Other analyses search for the critical factors that characterize successful constitutions, again with regard to growth and wealth and political stability as a prerequisite for both. Other studies analyze the impact of politics institutions and ideologies on real policy making.

Compared to institutional databases, there are only few datasets about ideologies available. One was developed by Berry et al. for the American states. Here are the references:

Berry, W.D., Ringquist, E.J., Fording, R.C., Hanson, R.L., 1998. "Measuring Citizen and Government Ideology in the American States, 1960–93." American Journal of Political Science 42, 327–348. Updated data 1960–2010: http://rcfording.wordpress.com/state-ideology-data/.

Summary

New institutionalisms in social sciences have a clear focus on institutions – and far less on ideologies. However, there are attempts to incorporate ideologies into theoretical and empirical analyses. A major challenge for both, theoretical and empirical work is to have a proper definition of institutions and ideologies – and to distinguish between them. Defining and distinguishing are basic prerequisites to make both concepts fruitful in explaining real-world phenomena.

While there is broad consensus about the logic behind institutions, the picture is more blurred when it comes to ideologies. However, ideologies – referring to Denzau and North – can be seen as a different kind of shared mental models. They can be modeled as the underlying nonformal but logically consistent set of ideas and belief about the structure of the world – and how the world should be structured. Therewith, ideologies are some kind of evolutionary foundation for the set of formal institutions framing the society, the economy, or even organizations. Accordingly, changes (or shifts, respectively) in the underlying ideology can trigger institutional change.

Although there are first results that suggest the importance of formal (and informal) institutions on the performance of political and economic organizations, more work has to be done to explore if and how relevant ideologies are for the new institutionalisms in political science, sociology, and economics.

Abstract

The sociology of ideology is part of the general sociology of social beliefs and knowledge. Ideology singularizes itself in the general realm of beliefs not only by the centrality it accords to the nature and the becoming of societies but also by its relational dimension traditionally defined in terms of antagonism and struggle. If the sociological analysis of ideologies was initially developed on a macrosociological level, sociologists have tended progressively to abandon the idea of ideology as a homogeneous and unified belief system for a more localist approach.

Sociological concepts such as *ideology* have multiple lives. Once considered as crucial for the analysis of political and social systems, the concept has since been severely criticized from different perspectives. For some, coming mainly from post-structuralism and postmodernism, it implies a much too rigid demarcation between knowledge and belief, and a too naive conception of truth as correspondence. For others, coming from varieties of comprehensive sociology, the idea of 'false conscious' prevents from understanding the deep feeling of conviction that generally characterizes the relation of any individual to his own beliefs. And most contemporary sociologists agree that the archipelago of ideologies is much more complex than anticipated. The traditional map of large-scale 'systems of interpretation of the historico-political world' (Aron, 1964) does not fit anymore with the complexity and multiplicity of contemporary collective beliefs systems. So should we, as sociologists, definitely forget about ideology? Although the 'end of ideology' (Bell, 1960; Lipset, 1960) has been regularly announced since the end of the twentieth century, it is obvious that sociologists still use the concept to address research questions related to various areas: gender identities (Davis, 2007), values and interests in entrepreneurial science (Abraham and Balling, 2012), professional demarcation (Gieryn, 1983, 1999) and professional politicization (Coulangeon et al., 2012), public opinion and organizational competition (Barnett and Woywode, 2004), religious or political radicalism (Rhys, 1996; Rydgren, 2007), and terrorism and warfare (Turk, 2004; Tosini, 2009).

The first section briefly returns to the origins of the sociological use of the concept of ideology. If the concept preexists to sociology as discipline through the theory of the *idola* developed by the English philosopher Francis Bacon or the French tradition of the *Idéologues* led by Destutt de Tracy, its elaboration starts with Marx's writings and their immediate readers (among them Karl Mannheim). The second section focuses on the specificity of the ideological phenomenon. Just like many other big terms in sociology (*action*, *society*, *community*, etc.), Ideology seems to defy a precise and unique definition: process of production of meanings, signs, and values in social life; process of naturalization of social life; forms of thought motivated by social interests, propaganda, and systematically distorted communication; action-oriented set of beliefs, etc. These are only few examples from a long list of possible definitions (Eagleton, 1991; Van Dijk, 1998). The discussion of classical and contemporary sociological literature allows us to specify the ideological phenomena through three interdependent aspects. The last section focuses on the variety of modes of sociological explanation of ideology. Only few explanatory schemes give real access to the social mechanisms behind its acceptance and diffusion. They generally suppose to adopt toward the ideological beliefs a similar attitude as M. Weber for the magic beliefs or, in a certain extent, Durkheim for the religious ones: reconstruct the 'meaning' of the ideological belief for the social actor (Boudon, 1989).

Origins of the Sociology of Ideology (Marx, Mannheim)

The origin of the sociological use of the concept of ideology can be found in Marx's writings on the coup d'état of Louis Bonaparte (Marx, 1852). The important part of his demonstration consists in showing how, once the riots of June 1848 were over, dissensions within the *parti de l'ordre* – the right wing of the French parliament – helped make this coup d'état unavoidable. This party was composed of many fractions that all, Marx affirms, have a "superstructure of impressions, illusions, ways of thinking and some philosophical conceptions." To understand the origin of these 'ways of thinking' it is essential to identify the 'competition of interest,' the will of each fraction 'to restore its own supremacy.' The landed aristocracy and the industrial bourgeoisie develop different political representations: the former theorizes the benefits of the absolute monarchy, the latter those of parliamentary monarchy. In both cases, Marx suggests, they tend to give a general value to 'ways of thinking,' which actually constitute only the formulation of objective conditions that ensure the domination of a social group over another. Hence the strong relation between analysis of ideology and analysis of the struggle between social groups. Defined as prevailing ideas, ideologies are identified to those of a group seeking to preserve its social domination through their naturalization. The analysis of Marx does not end with this comparison between particular 'interests' and 'ways of thinking,' it also underlines the way in which certain individuals embody ideologies. Describing the 'ideologists' consists mainly for Marx in studying the

'writers,' the 'press,' and more largely 'representatives' of the bourgeoisie. In the present case, the inability of these ideologists to express the real opinion of those they should represent, shortly before the coup d'état, Marx points out, "the representatives and represented had become strangers to each other."

The argument is simple and easily acceptable: when an institution – here a political mode – appears in conformity with the particular interest of a social actor, individual, or collective, this actor generates, directly or indirectly, a whole set of ideas, representations, and theories intended to make the value of this institution acceptable by the majority – even if this value objectively makes real sense only for the social actor considered. When K. Mannheim looks back to this argument in *Ideology and Utopia* (1929), he presents it as a fundamental stage toward the formation of the sociology of knowledge: the first attempt to stress "the role of the position of class and the interests of class in the thought." This attempt rests however on a confusion between two conceptions of the ideology. In the first – particular conception – the 'ways of thinking' are 'mystification more or less conscious of the real nature of a situation whose exact recognition would not be in agreement with the interests' of the ideologist; they are reducible to a psychology of the interests, concern primarily the individuals, and are connected with lies on the moral level, or errors on the epistemological level. In the second – total conception – the same 'ways of thinking' are not 'illusions' deliberately maintained by the individuals according to their more or less immediate interests but elements of a total 'system of significance,' 'knowledge grown out of our experience in the real situations of the life.' One of the rare examples of ideological 'knowledge' in this 'total' conception suggested by Mannheim is the moral judgment related to the loan of money with interest. Formulated and assimilated by the Church like an ethical standard, the morally reprehensible character of the loan with interest becomes ideological, affirms Mannheim, since the social actors try to maintain it out of the social framework to which it is 'adapted': a precapitalist society based, economically and socially, on personal relations of intimacy. Through its attachment to this judgment, the Church expresses its difficulty of thinking social reality independently of a 'system of significances' adapted to a disappeared social framework from now on.

It is possible to read Mannheim's classical analysis on *Conservative thought* (1927) as an exercise of sociology of knowledge. Mannheim connects the spread of conservatism in Germany to three main factors: First, the affinity between the content of conservative thought – defined as a 'style of thought' oriented toward the concrete and qualitative dimensions of reality – and the aspirations of groups opposed to the advent of bourgeois capitalist society. Second, the phenomenon of social polarization reinforced by a middle class too weak to produce a 'synthesis' between extreme views. Third, the socially 'unattached' and economically unstable situation of German romantic intellectuals; a situation that renders them particularly receptive to political and social radicalization. Mannheim's study on *Conservative thought* can be seen as the German counterpart of the one conducted by Alexis de Tocqueville (1856) for France and its intellectuals.

Ideologies as Social Beliefs

This brief detour about the origins of the sociology of ideology suggests that traditionally sociologists associate the concept of ideology with products or properties of thinking shared by social groups. These ideas or systems of ideas have multiple possible forms (principle, theme, theory, myth, style, representation, doctrine, etc.). But whatever their forms, these are products or properties of thinking about which individuals collectively develop a deep feeling of conviction or commitment. Hence their general characterization as social beliefs or clusters of social beliefs. The difficulty that consequently arises is that of the specificity of the ideological phenomenon inside the general realm of social beliefs.

Ideologies and the Legitimate Social Order

Some recent examples of sociological studies of ideologies give us a good starting point for our discussion. Focusing on the interwar period in Austria, Barnett and Woywode (2004) analyze the Viennese newspapers over the period 1918–38. Newspapers are defined as 'organizations' and their relation as an 'ideological competition.' The sociological analysis distinguishes two main dimensions. First, the nature of ideology defined as the 'basis of political identity' of social groups in the Austrian society. Three general ideological 'positions' (*lager*) are identified corresponding roughly to political left (left radical, communist, radical socialist, etc.), center and bourgeois (democratic, Christian social, civil liberal, etc.), and right (patriotic, right radical, national socialist, etc.). Second, the evolving nature of the relation between organizations defined as 'ideological competitors.' The general thesis is that "the strongest ideological competition is likely to take place among close substitutes – adjacent ideologies that are too different to enjoy *esprit de corps* but similar enough to threaten each other's identity claims" (p. 1453). The tension between organizations is described as an ambivalent process merging two opposing tendencies: strong oppositional identity claims and regular attempts of frame alignment on competitors to attract their followers. Leaving the interwar for a more recent period, Rydgren (2007) recalls the emergence of the radical right in Western Europe over the last 20 years. He describes the 'ideological core themes' of this radical right mainly as sociocultural themes. The new radical right gives priority to 'national identity' and builds on the idea of 'ethno-pluralism' elaborated by the French *Nouvelle Droite*: "the notion of ethno-pluralism states that, to preserve the unique national characters of different peoples, they have to be kept separated. Mixing of different ethnicities only leads to cultural extinction (…) contrary to the traditional conception of racism, the doctrine of ethno-pluralism, as such, is not hierarchical: different ethnicities are not necessarily superior or inferior, only different, incompatible, and incommensurable" (p. 244). The emergence of this radical right manifests itself also by an attempt to recode the political space in terms of a struggle against the collusion of all established parties. This oppositional strategy leads to an apparent paradox: generally described as authoritarian, the radical right parties, such as the *Front National* in France, generally present themselves as the new champions of

'true democracy,' which take into account the interests of the common man.

These two brief examples show how the concept of ideology singularized itself in the general realm of beliefs. First, by the centrality it accords to the nature and becoming of society. Ideologies are beliefs or cluster of beliefs about the legitimate political and sociocultural order. Second, by the relational dimension attached to it and generally defined in terms of 'antagonism,' 'struggle,' or 'opposition.' The ideologist and the ideological organization oppose 'what is' to 'what ought to be.' They propose more than a simple interpretation of society: a program to transform it. This transformation may have multiple directions. When Mannheim defines *ideology* vs. *utopia*, by making the former an exclusive vector of conservatism where the latter would be progressivist, he only preserves the initial views of Marx. This vision of the ideology is, however, too restrictive. Not only are the ideologies not the prerogative of the conservatives – Parsons (1959, 1964) distinguishes four types of ideologies: conservative, counter-, reform, and revolutionary – but one ideology can, according to social and historical circumstances, serve various social purposes. Liberalism, socialism, or various contemporary forms of nationalism (Gellner, 1983; Birnbaum, 1997) appear, at a given time of their history, as vectors of social emancipation as well as general principles of immobilism or conservatism.

This double referent – sociopolitical and practical – makes it possible to distinguish between ideology and other types of beliefs, religious ones in particular. The ideologist speaks in the name of reason. Its truth claims positive values of rationality and is diffused by suggestion, persuasion, but much more rarely by revelation. Many sociologists (Bendix, 1964; Gouldner, 1976) thus establish a strong parallelism between the development of the ideologies at the end of the eighteenth century and the emergence of modernity defined as a 'rational' social order in opposition to a 'traditional' social order. This by no means implies that the religious elements disappear from the ideological discourse. As religion exists as a 'cultural system' it may constitute a 'shaping force for political life' (Rhys, 1996). In France, the recent public debate on the reform of bioethics laws (Dubois, 2012) or the public demonstrations against the legalization of gay marriage show that coalitions of religiously based activists regularly mix religious and political arguments. They use the cultural force of religious symbols to attempt to modify the political agenda. From a more radical perspective, the ideologies of numerous fundamentalist movements around the world build on selective and 'innovative' interpretation of sacred texts. Such interpretations contribute to produce a culture of political violence in the name of creating or restoring a legitimate social order (Turk, 2004).

Disassembling Ideology: from Macro- to Microsociology

If the sociological analysis of ideologies was initially developed on a macrosociological level (Apter, 1964; Geertz, 1964), it is becoming increasingly microsociological. This is explained by the fact that sociologists have tended progressively to abandon the idea of ideology as a homogeneous and unified belief system. When Aron (1964) analyses the contemporary political modes, he characterizes ideology as an explicit system of beliefs developed around a core of descriptive and prescriptive proposals. The dominant features of this system are unity, coherence, and totalizing character – the capacity to potentially bring a response to any interrogation. Whatever its heuristic value, this representation of ideology as a 'monolithic' unified block rarely fits with empirical data. Ideological beliefs contain generally irreducible tensions and contradictions. This conclusion is drawn from several perspectives. First, from observation of ideological production itself. Sociologists insist on the 'compromises' and the 'adjustments' necessary to hold in a same unit theoretical logic and the principle of action (Seliger, 1976). They describe the production of ideology as a 'tinkering' process during which the ideologist tries to satisfy the demand of meaning of his public without ever being able to exert a true control on his resources (Bourricaud, 1980). Second, it is drawn from observation of the organization of ideological components. As recently emphasized by Achterberg and Houtman (2009), sociologists cannot presuppose the coherence of ideological belief systems: "knowing someone's values on economic matters does not lead to a correct prediction of what one will think about cultural matters. There is no or very little coherence between the two value dimensions" (p. 1650). Beside this multidimensionality, the degree of coherence of ideology is not socially uniform. Research demonstrates that ideological components are more consistently ordered within the cultural, intellectual, and political elite than in other social groups. Finally, it is drawn from observation of the evolution of ideologies. Modern ideologies are different from the ones observed a century ago. For Boudon (1999), modern ideologies evoke the image of archipelago, while the old ideologies evoked rather the idea of a continent. "We have ideologies, writes Boudon, as to what should be done about unemployment, educational opportunities, fighting against crime or drug addiction and on a myriad of subjects, as well as how it should be done. But these theories are weakly related to one another. We have ceased to believe that they could be derived from an all-encompassing theory. We have all kinds of local ideologies; we no longer believe in general ideologies."

These local ideologies are sometimes defined in terms of professional belief systems. In his study on 'boundary work' in science, Gieryn (1983) observes that when scientists confront the public, they endow science with characteristics selected for an ability to advance 'professional interests.' They use available 'cultural repertoires' to produce profitable 'ideological self-descriptions.' Hence the risk for the sociologist to be too naive about these distorted self-descriptions. More recently, following the Straussian definition of professional arenas as 'political space for debate,' Coulangeon et al. (2012) consider as crucial not to limit the analysis of professional ideologies to political or trade union arbitrations or publicized moments of collective action. Using a questionnaire survey of French police officers of all ranks, they identified the 'ideological dissensions' within the French police on how police work should be carried out. Three general ideological positions are discussed – repressive, median, preventive – and the observed dominance of the first

(repressive) substantiates, according to the authors, "an ideological closeness between profession and the (political) right" (p. 375).

Ideology and Scientific Knowledge

As Gieryn stresses the difference between 'self-description' and the objective reality of practices and values, he reaffirms the traditional distinction between ideology and knowledge. Ideology involves elements of distortion from reality. Well-known authors such as Marx, Mannheim, Parsons, Althusser, Aron, etc. converge to consider ideologies as forms of 'distorted knowledge,' 'false beliefs,' and 'deviation compared to scientific objectivity.' The ideologist produces a representation of the social order, he wishes to be socially considered as the unique depository of a true meaning, but both representation and meaning are objectively illusory. Despite this relative consensus on the demarcation between ideology and knowledge, the reality of the ideological phenomenon is more complex. The ideologist shares in fact with the social scientist the will to produce a general discourse on society. It is not infrequent that certain sociologists consider their analysis as the methodical prolongation of a preexistent ideological point of view. The historical examples are numerous and well known: openly conservative, Frederic Le Play theorizes the traditional form of family – *famille souche* – as 'the social unit per excellence'; convinced liberal Herbert Spencer proposes an evolutionary model closely associated with the diffusion of 'social Darwinism,' etc. Inversely, a sociological theory or paradigm conceived independently of any ideological commitment can, when it is exploited out of its immediate context of validity, generate ideological skid. The mechanism is once again well known: it consists mainly to project on the theory or sociological paradigm the totalizing character of ideologies and by doing so asks those theories and paradigms to answer any possible interrogation.

The significant development, since the beginning of the 1970s, of the social studies of sciences made it possible to highlight the importance of economic, cultural, and political factors on the course of scientific research. These studies show on the one hand how the scientific institution satisfies a social demand, and on the other hand how the scientists integrate in the course of their cognitive practices different cultural elements, in particular, extrascientific 'interests.' These studies are now part of a general program of political sociology of sciences (Frickel and Moore, 2006). Recent works by Kinchy et al. (2008), Lave et al. (2010), and Abraham and Ballinger (2012) try to show how new variants of liberalism (neoliberalism) influence directly or indirectly the content of scientific expertise in the biotechnology area. For the latter, the evolution of carcinogenicity testing systems coincides much more with the 'interests' of the pharmaceutical industry and drug regulatory agencies than with public-health protection. Oreskes and Conway (2010) claim that controversies over tobacco smoking, acid rain, the hole in the ozone layer, or global warming are not only strictly rational disputes about the robustness of empirical proof but also ideological controversies within the scientific community.

Explanatory Schemes of Ideologies

How should we explain the production and diffusion of ideologies? Sociologists have proposed numerous explanatory schemes. Without trying to be exhaustive, it is useful to briefly describe four of the most common schemes.

One key aspect of the production and diffusion of ideology is frequently related to the socialization process. Socialization is a learning process that begins shortly after birth for its primary dimension. Studies on 'gender ideology' (Bolzendahl and Myers, 2004; Davis, 2007) – that is, cluster of beliefs regarding the appropriate roles of women and men in society – emphasize the importance of personal and familial dimensions. Young women with high self-esteem or personal confidence have more probability to break away from traditional definitions of 'gender roles.' But children's exposure to egalitarian behavior models seems as much as important as strictly personal factors: growing female labor participation contributes to socialize children to more egalitarian methods of dividing household responsibilities between women and men. The socialization process is also explicitly referred to in its secondary dimension by sociologists of professions. Observing the unequal distribution of ideological positions within the French police, Coulangeon et al. (2012) consider that the daily exercise of a job acts as a socialization process through which opinions are progressively reconfigured: "giving orders, maintaining public order, making arrests and driving retain a positive effect on adherence to a repressive ideology and a repellent effect on adherence to a preventive ideology, while contact with the public places police officers on the preventive side" (p. 371).

A second factor regularly cited by sociologists of ideology is *social interest*. As previously reminded, the Marxist tradition associates the production of ideology with the ruling class interests that are supposed to dominate the conscience of other social groups. This causal approach of beliefs claims that if the dominated class accepts blindly social representations that contribute to reproduce its subordination, the dominant class generates social representations which maintain its domination. The example of the study of the 18 *brumaire* shows, however, that Marx develops, in certain empirical writings, a less simplistic representation of the production process of ideologies. They are described as more than strategical theories imposed to social actors: representations of limited validity inspired by reality such as it can be observed from a given social position. Although the influence of Marxism in sociology has greatly declined, the notion of social interest associated with economic and cultural position remains sociologically useful. Focusing on scientific professions, Gieryn (1983, 1999) observes that scientists have at their disposal multiple repertoires to produce ideological descriptions of science. The role of interests is to guide the selection between those repertoires: "Ideologists are able to endow science with just those characteristics needed to achieve professional and institutional goals, and to change these attributed characteristics as circumstances warrant" (1983: p. 792). Ideologies are conceived mainly as 'professional means' to gain authority, power, and resources. In their analysis of the ideological competition between Austrian newspapers, Barnett and Woywode (2004) expressly relate the

ideological positions to different kinds of interests. During the interwar period, the political center, for example, included secular liberal (according to the nineteenth century definition) capitalist interests. And a centrist organization such as a purely bourgeois newspaper shows a general tendency to sacrifice its political role in order to pursue its material interests. Building on Converse's theory (1964), Achterberg and Houtman (2009) consider that economic and cultural interests interact to affect ideological (in) coherence: "If a person is in a weak position (which means: low level of education, low income, high risk of unemployment) and suffers from economic insecurity, he or she is more inclined to be pro-welfare state, pro-state intervention in the economy, pro-financial redistribution and have egalitarian values" (p. 1643).

A third factor that drives the production and the diffusion of ideologies is conceived by sociologists in terms of 'passions' or 'feelings.' In his *Trattato di sociologia generale*, Pareto (1916) considers that the ideologies – he speaks of 'derivations' – are primarily the effect of deep feelings remaining inaccessible to the conscience. More precisely Pareto affirms that the social actor wants to be convinced of the value of his passion, and produces derivations for this purpose. The ideologies would be thus the epiphenomenal expression of dominant passions. If the Paretian model of ideology remains generally ignored by the contemporary sociological tradition, sociologists still use the category of feeling in various contexts. The emergence and success of contemporary radical ideologies are sometimes described as the consequence of relative deprivation feelings. As emphasized by Merton (1964), the concept of relative deprivation comes from the study of the 'sentiments and attitudes' of American soldiers. Relative deprivation theory focused on feelings caused by disappointing comparisons with one's own past or with social reference groups. Rydgren (2007), for example, considers that the feeling of frustration is related to the emergence of the new radical right-wing parties in Europe. The 'losers' in the postindustrialization processes are described as 'anxious,' 'bewildered,' 'insecure,' and 'resentful': "sentiments that may be channeled into support for policy proposals that stress the need to return to the traditional values of the status quo ante" (p. 248). Following the same general path, sociological studies of hate crimes and terrorism indicate that ideologically radical behaviors are not a direct response to poverty or social disadvantage but much more to "feelings of indignity and frustration developed in repressive political environments" (Turk, 2004).

Finally, a fourth general type of sociological explanation consists mainly to adopt toward the ideological beliefs a similar attitude as M. Weber for the magic beliefs or, in a certain extent, Durkheim for the religious ones: reconstruct the 'meaning' of the ideological belief for the social actor by seeking the system of reasons or preferences that this actor produces to justify to himself his adhesion. The rationality considered by the sociologist is not reducible to an instrumental one but is also quite different from the 'derivations' described by Pareto. The sociological analysis opens on a set of 'subjective reasons' that represent the necessary conditions of the ordinary thought. These reasons are of general but nonuniversal validity and manifest themselves on different levels: utilitarian, axiological, traditional, or epistemic. Inspired by studies of Downs (1957) and Simon (1982), the restricted theory of the ideology elaborated by Boudon (1989) stresses the necessary 'comprehensive' dimension of the sociological analysis. When some people adopt statements or ideas that appear to the sociologist as false or doubtful, the sociologist has to consider that this may derive from the fact that, given the situation, these beliefs are to them the conclusions of reasons they perceive as 'strong.' This strategy is directly linked to an active theory of ordinary knowledge: the social actor produces knowledge, not simply by contemplating reality, but by interpreting it from its social position, and more generally from questions that are only seldom directly provided by reality itself. This last approach has a certain number of objective advantages. In particular, it makes it possible for the sociologist to give an account of important subjective data: the feeling of conviction and not of interiorization that generally characterizes the relation of any individual to his or her own beliefs.

Ignorance, History of Concept

Barbara Hoenig, Innsbruck University, Innsbruck, Austria

Abstract

The term 'ignorance' designates nonknowledge, what is unknown, or absent in empirically valid knowledge. Starting from a distinction of kindred concepts in different scientific disciplines, particularly the concept's role in theories of social action, in theories of knowledge, and in organizational studies are considered. Finally, current developments in agnotology and in the sociology of ignorance are discussed.

Proverbs like "ignorance is bliss" and "what you don't know can't hurt you" reflect the fact that one should be aware of what not to know. In scientific discourse, ignorance designates what is unknown, and absent in empirically valid knowledge, in the sense of nonknowledge. Thus, ignorance is held distinct both from the act of 'ignoring' what is known, and from 'error', 'risk', and 'false beliefs' as forms of imperfect or limited knowledge (Moore and Tumin, 1949: p. 788); rather, ignorance can be regarded as a "more or less hidden component of situations usually discussed in other terms" (Moore and Tumin, 1949: p. 795). Ignorance's dynamic role in social change seems to depend on the recognition of its existence and a subsequent searching for more adequate knowledge. In a similar vein, the specification of ignorance has been regarded as prerequisite to the acquisition of knowledge (Merton, 1987). As subsequently will be shown, ignorance is related to kindred concepts in different scientific disciplines; more specifically, the author takes account of the role of ignorance in theories of social action and in theories of knowledge and science studies. After outlining how ignorance has been reflected as strategic resource in organizational contexts, some recent developments in agnotology and in the sociology of ignorance are considered.

Ignorance and Kindred Concepts

Ignorance and related concepts form an important phenomenon in several neighbor disciplines of the social and behavioral sciences. Think of Freud's 'unconscious' as path-breaking notion in psychology and cognitive science till today: He coined the term in trying to understand which type of nonconscious knowledge is involved in forgetting a word, producing a linguistic lapse, or understanding a joke (Freud, 1901). Ignorance is close to terms such as oblivion, secrecy, censorship, and taboo as well, which were so central in the works of some social anthropologists (Douglas, 1966). Complex relationships between ignorance and actors' rational choices are reflected in economics, where incomplete knowledge and asymmetric information embodied in situations of interdependent decision making creates dilemmas and opportunities for strategic action (Schelling, 1960). In political science, the role of discretion for bureaucratic autonomy has been a topic in discussing how politicians make use of laws to shape the policy process (Huber and Shapin, 2002). In philosophy, skeptical reasoning about knowledge resulted in critically articulating a remarkable amount of ignorance implied in ordinary language (Unger, 1975). In political theory, the concept 'veil of ignorance' has been used in a thought experiment for granting fair, unanimous decisions, assuming that in a fictional situation of decision making, rational actors' reasoning on social order would be oriented toward what anyone would wish, do, or agree with, under the condition that actors would not know about their own social position in it (Rawls, 1971). In science and technology studies, the assessment of more expectable, calculable 'risks' has given rise to accounting for ignorance as well, while kindred 'uncertainty' has been understood as a subbranch of it (Smithson, 1989: p. 9). According to Michael Smithson's taxonomy, ignorance is related both to relevance and error, the latter indicating distortions or incompleteness in knowledge; in the formal sciences, incompleteness is reflected in terms of absence, ambiguity, probability, vagueness, fuzziness, and nonspecificity (Smithson, 1989: p. 9). Bearing on ignorance as a social scientific concept, distinctions such as 'structural' (Moore and Tumin, 1949), 'specified' (Merton, 1987), 'science based' (Ravetz, 1987), or 'strategic ignorance' (McGoey, 2012) have been suggested. Recently, Andrew Abbott has focused on the need to specify the quality of ignorance one is subject to in order to enjoy the positive function of several 'varieties of ignorance' (Abbott, 2010). Investigating ignorance as manifest in different sources of scientific knowledge, he has drawn a distinction between three types of ignorance connected with corresponding actor groups involved in knowledge production: the 'amateur's ignorance' of central cognitive skills, the 'professional's ignorance' of collateral literature, and the experts' 'synthetic ignorance' of facts, as an inability to perceive them other than in the light of one's own paradigm or theory (Abbott, 2010). While most social scientific approaches toward understanding ignorance were independently developed by individual scholars, in the following the author discusses some of them either as part of social theories of action or within the frame of a sociology of knowledge.

Ignorance in Theories of Social Action

Very often in life, one takes action on the basis of rather little knowledge, concerning both structural conditions and consequences of one's activities. Ignorance affects one's capacities to act in a social structure constraining one's choices; it is also

bound to unknown effects, contingent outcomes, and unanticipated consequences of action, in contrast to calculable risks, controllable effects, and desirable aims. Different schools or paradigms of social theory have found divergent answers to how ignorance is related to social action, and mostly they have dealt with it as a rather implicit issue of concern (Schneider, 1962; Gross, 2007). As Louis Schneider (1962) has shown, the 'classics' of social theory have reflected ignorance mainly in terms of mystification and in sharp contrast to notions of enlightenment, truth, and knowledge; While Marxism and in part Karl Mannheim's sociology of knowledge focused on the cognitive distortion of scientific truth by false consciousness and ideology, Max Weber regarded science as a way of demystifying the magic ignorance of the world by intellectualization and rationalization (Louis Schneider, 1962). In contrast to the 'savage' who 'knows incomparably more about his tools', although for whom magical powers existed as well, today one usually does not have much knowledge about, but rather 'count on', the behavior of technical means such as the streetcar, believing that "one can, in principle, master all things by calculation" (Weber, 1917/1919: p. 87). Georg Simmel reflected ignorance as part of an increasing discrepancy of objective and subjective culture; as one of few classical sociologists, he dealt with ignorance as inevitable part of the 'secrecy' inherent in social relations (Simmel, 1908).

Wilbert E. Moore and Melvin Tumin (1949) acknowledged the inescapable character of ignorance intrinsic to social organization with the aim of examining its structural functions in varying institutional contexts. According to them, one function of ignorance is maintaining privilege in asymmetric power relations as between lays and experts, specialists and potential competitors, and in ethnic and class stereotyping as well. As specific kind of institutionalized ignorance they mentioned the case where ignorance of future chances is institutionally used "as a device to create anxieties and spur activity in a competitive system" such that a worker is "expected to be motivated by his insecurity" (Moore and Tumin, 1949: pp. 793f.). However, they also acknowledged institution's ignorance of an individual's irrelevant personal characteristics as precondition for preserving fair competition, for instance, in recruitment by bureaucratic organizations or in peer review procedures of science. Apart from that, the attractiveness of any 'new experience' in life depends on one's ignorance or uncertainty of its outcome (Moore and Tumin, 1949: pp. 793f.). Robert K. Merton is one of the most important theorists focusing on the role of ignorance in social action: in discussing unanticipated consequences of purposeful action (Merton, 1936), in reflecting the role of serendipity (Merton and Barber, 2004), and 'specified' ignorance in scientific progress (Merton, 1987). Unanticipated consequences may arise through the limited knowledge about bases of social action and a correct anticipation of its consequences. As barriers to correct anticipation, Merton mentioned not only ignorance, but also error, imperious immediacy of interest, basic values, and self-defeating prediction (Merton, 1936). Moreover, he dealt with the role of ignorance in the dynamics of scientific discovery and in the relationship between empirical research and sociological theory, as indicated by the 'serendipity pattern' in science, designating "the fairly common experience of observing an unanticipated, anomalous and strategic datum which becomes the occasion for developing a new theory or for extending an existing theory" (Merton, 1957: p. 104).

Symbolic interactionists and phenomenological sociologists have produced interesting accounts of ignorance as well (Berger and Luckmann, 1967; Schütz and Luckmann, 1973). Underscoring the idea that social interaction and communication are made possible by actors sharing a stock of knowledge, meanings of significant symbols, and negotiated definitions of situation, they also have mentioned 'structures of ignorance' as part of relative or even fundamental opacities in everyday life and as 'potential knowledge' (Schütz and Luckmann, 1973). However, the empirical case of nonshared experience and asymmetries in knowledge seems to posit an analytical problem for phenomenological approaches (Smithson, 1989: p. 235). In contrast to that, Erving Goffman's (1959) metaphor of the backstage accounts for the fact that some types of social interaction are only possible when social actors are at least partially ignorant of other's intentions. Ethnomethodologists (Garfinkel, 1967) and social constructivists tried to explicate actors' practical competencies of taking action in everyday life, underscoring its nondiscursive, 'tacit dimension' (Polanyi, 1966) as precondition for successfully accomplishing it. Thus, they regarded ignorance as basic characteristic of microsocial interaction and of social reality in general.

Ignorance in Theories of Knowledge

Similar to his distinction of manifest and latent functions of social action, Merton (1987) has characterized ignorance's function in science as a social institution, drawing on the importance of its recognition that turns formerly unrecognized then to 'specified' ignorance. Contrary to the normative expectation that an individual scientist shows humility through confessing ignorance by acknowledging one's knowledge limitations, Merton clarified the cognitive value of specifying what exactly is not known: According to him, specification of ignorance precedes scientific problem finding, a process of selectively perceiving complex phenomena in a dialectic of awareness of some and negligence of other aspects (Merton, 1987: p. 8). He illustrated that practice by discussing successive stages of theory development in the sociology of deviance from the 1920s onward. Moreover, he was interested in whether scientific disciplines differ in their extent of routinely specified ignorance and how this affects the growth of knowledge in these (Merton, 1987: p. 8). At quite the same time, the term 'science-based ignorance' has been coined by philosopher John Ravetz (1987) who developed a similar thesis in talking about relevant, usable forms of nonknowledge.

The classical paradigm of the sociology of knowledge, formulated by Karl Marx and Karl Mannheim and specified by Merton, focuses on the relationship of cognitive or 'mental productions' to designated 'existential bases' as given by social structure. In trying to articulate a parallel paradigm for the sociology of nonknowledge, David Weinstein and Michael Weinstein asked "why and how people exclude certain cognitions and judgments from their awareness" (Weinstein and Weinstein, 1978: p. 152). They defined their suggested metatheory in terms of 'ground' (epistemologies or general theories

of knowledge), 'resultant' (types of actor's nonknowledge involved), and an intervening process between both, in which the distorted or inadequate cognition arises (Weinstein and Weinstein, 1978: p. 154). Concerning the epistemological ground dimension for nonknowledge, they made a distinction between 'need-grounded' and 'possibility-grounded' conceptions of nonknowledge, the first term indicating universal motivators of social action, the second term bearing upon not necessarily universalistic options, purposes, and goals of human action. Resultant types of nonknowledge they interpreted in analogy to these types of grounds, as 'need-grounded misinterpretations', on a continuum ranging from falsification to distortion presupposing some knowable true description of social life, versus 'possibility-grounded inattentions', neglect, and inadvertence, assuming a 'standard field of possibilities' rather than only one true description of a situation. The dynamic component of the suggested paradigm referred to "a process through which mistaken cognition or inattention takes place" (Weinstein and Weinstein, 1978: p. 156); as examples of explaining mistaken cognition or the narrowing of possible alternatives, Freudian ego-defense mechanisms or social sanctions in structural-functionalism were given. Although in Weinstein and Weinstein's variegation of the Mertonian paradigm for the sociology of knowledge particularly the conceptualization of knowledge bases is confusing, it becomes apparent that the sociology of nonknowledge proposed shall not restrict itself to institutional analyses of social structure but to directly make judgments on the meaningfulness of nonknowledge's cognitive content (Weinstein and Weinstein, 1978: p. 159).

The authors' explicit cognitive interest and their strong focus on describing ubiquitous processes of not-knowing characterizes more recent constructivist sociology of scientific ignorance as well. For instance, Karin Knorr-Cetina (1981) emphasized that knowledge and ignorance, and the criteria by which they are established, are 'socially constructed' in interaction processes and negotiations among actors that are highly contingent, contextually and situationally determined, and to a large extent dependent on the tacit, inexplicable, and implicit character of practical know-how. The interest in the formal structure of that social fabric has inspired lots of empirical studies on knowledge production in microsocial scientific contexts such as laboratories. Within the wide range of the sociology of knowledge, the implied epistemological relativism of that position remains questionable; in addition, the focus on local practices of knowledge production often neglects the influence of institutional contexts and communal procedures of knowledge evaluation on what counts as knowledge. From the perspective of an institutionalist sociology of the sciences, Richard Whitley (1984) has dealt with the question of how ignorance, uncertainty, and the organization of scientific fields affect one another, distinguishing between 'technical' versus 'strategic uncertainty'. While the former refers to scientists' disagreement on the reliability and understanding of research techniques, strategic uncertainty indicates disagreement about and pluralism of intellectual priorities, significance, and ways of tackling research problems. According to Whitley, high technical uncertainty usually entails high strategic uncertainty, but the reverse does not generally hold. Since one of ignorance's most important aspects refers to its function in institutional contexts, here the author takes a short digression accounting for the role of ignorance and its strategic uses as a resource in organizations.

Strategic Ignorance as an Organizational Source

When Schneider (1962) has particularly drawn attention on structural functionalism's usefulness for analyzing the functions of ignorance in institutional contexts, he did so by developing what Abbott (2010: p. 186) later has called a 'liberating' view on ignorance: aiming at specifying those conditions where ignorance might lead to positive, more democratic results. Apart from taking ignorance's protective function exercised in the context of immediate interaction, or its consequences for specific persons in a situational interaction context into account, like in parent–child interaction or a physician–patient relationship, Schneider thought of more institutionalized examples of ignorance's consequences for a wider social structure. Thus, he mentioned Burton Clark's (1960) discovery of the 'cooling out function' of higher education institutions, as informal practices of discouraging and 'adjusting' students' expectations toward aspiring less ambitious goals, and Peter Blau's (1955) study on social dynamics in bureaucratic institutions, in which 'gain through indirection', as one form of ignorance, is often an implicit practice of concern. In his study, Blau outlined how institutional requirements can be reached by bureaucratic mechanisms neutralizing possible bias of actors that, unwittingly or not, might influence decision-making practices by prejudices against minorities. "In functional terms, a social pattern with the latent function of impartiality, statistical records, was more effective than a different pattern with the same manifest function, antidiscrimination rules. Since latent function is defined as an unintended consequence, the concept implies that the social behavior involved is motivated by factors other than the function under consideration" (Blau, 1955: p. 81). To this insight Schneider added the relevance of ignorance involved, conditioning more effective, nondiscriminatory placements, when bureaucratic actors "simply did not know that their action was bringing those things about" (Schneider, 1962: p. 501).

In the sociological study of organizations, ignorance has been considered as fundamental resource of any bargaining relationship between strategic actors, characterizing social power as their structural capacity to act by controlling 'zones of uncertainty' (Crozier and Friedberg, 1977). James March and Herbert Simon identified organizational norms for dealing with ignorance and uncertainties, anomalies, and risk, in constructing a self-confirming environment by 'absorbing' particular questions, inquiries, or communications about these (March and Simon, 1958). Taking the 'organized anarchy' of decision making at the university as an empirical example, Michael Cohen et al. (1972) formulated their 'garbage can model of organizational choice'. The authors underlined that under conditions of uncertainty, indicated by unclear technology, fluid participation, and problematic preferences, decision-making practices in organizations are more complex than suggested by classical analyses of rational action in these structural contexts. Rather, they suggested conceiving these as

contingent outcomes of four intersecting variables: a stream of choice, of problems, of energy from participants, and a rate of flow of solutions. Although Smithson's attempt to reconcile formal with social and behavioral sciences sometimes appear as rather abstract analysis, those interested in further research on ignorance in organizational research may find useful hints there (Smithson, 1989: pp. 239ff.).

Similar to these early findings in the sociology of organizations, recent science and technology studies have attempted to identify organizational strategies for constructing ignorance by the denial, dismissal, diversion, and displacement of 'uncomfortable knowledge' (Rayner, 2012) in tension or outright contradiction with self-consistent institutional definitions of situations. Linsey McGoey (2012) has investigated the strategic use of ignorance as part of organizational pressures where organizations' members seek to preserve and cultivate ignorance rather than to dispel it. She has analyzed strategies how members mobilize strategic unknowns of a situation as a tool of social control, command of resources, denial of liability, and assertion of expert control in the face of unpredictable outcomes. In contrast to Abbott's (2010) emphasis on different qualities of ignorance, and complementary to his remark that scholarly practices of articulating knowledge claims are accompanied by those of acknowledging ignorance, McGoey underscored the need to take scales of ignorance into account in order to recognize its value as an organizational resource: "(S)trategic ignorance is often more institutionally advantageous the more widely it is individually mobilized … because of the shared willingness of individuals to band together in dismissing unsettling knowledge" (McGoey, 2012: p. 570).

Agnotology and the Current Sociology of Ignorance

In public debates on science and technology, for a long time ignorance has mainly been considered as the lay's counterpart in relation to an expert's knowledge. Since the 1970s, however, both new social movements' critique of technological risks and endogenous developments in science studies have contributed to an emerging view of ignorance as inherent part of scientific development (Wehling, 2001: p. 470). Meanwhile, social scientific research on ignorance has rapidly grown to an interdisciplinary research field, 'agnotology', with the explicit intention to establish scientific accounts of formerly unrecognized knowledge (Proctor and Schiebinger, 2008). It is constantly fed by an abundance of empirical studies, many of them inspired by a constructionist sociology of knowledge. These have analyzed the emergence, discovery and consequences of scientific ignorance, like in human genetics and biotechnology, in public incidents with substances like chlorofluorocarbons, dichlorodiphenyltrichloroethane, and dioxin, or consequences of new technologies (for instance, Böschen et al., 2010). In addition, one can recognize an increasing interest in the societal dimensions of ignorance as inevitable part of modern knowledge societies (Luhmann, 1992; Ungar, 2008). Three aspects of these rather recent developments in a sociology of ignorance shall be considered here: the 'knowledge–ignorance paradox', the 'right not to know', and different 'epistemic cultures of nonknowledge' as dimensions of an increasing politicization of ignorance.

Particularly, Ungar has characterized a so-called knowledge–ignorance paradox evolving from contradictory dynamics of knowledge societies and its consequences as well. He indicated that, as inevitable by-product of the specialization pressures modern knowledge workers are subject to, their production of more specialized knowledge results in more general ignorance as well, entailing increasing entry costs and speech barriers to other knowledge domains (Ungar, 2008). The "shifting balance between personal expertise and common knowledge" goes hand in hand with an "increased reluctance to pursue additional information and a concomitant decline in the stock of general knowledge" (Ungar, 2008: p. 312). Focusing on functional knowledge deficits as cases where ignorance definitely is no bliss, Ungar also identified 'chains of ignorance', presumably consequential classes of ignorance that would require reversals throughout these chains in order to critically combat an overall debasement of public discourse (Ungar, 2008: p. 314). As part of the marketing of ignorance as a social problem, particularly successful in coalescence with social movements or moral panics, he identified claims referring to embedded ignorance found in specialty domains, ignorance of medical information, and the special kind of ignorance of the young; young people as a group are more often than others targeted by 'do not die for ignorance' actions, like in antitobacco campaigns, with significant moral undertones; as Ungar remarked, similar to the case of medical ignorance, the problem of ignorance here is often secondary to the real social problem. Ungar's interest in the societal dimension of ignorance within knowledge societies could fruitfully be deepened by future research taking the social stratification of access to knowledge, and nonknowledge, into account.

However, one can also imagine potential situations in which ignorance indeed may be bliss. Both predictive genetic testing and genetic engineering of children indicate areas where it might not only be 'better not to know' (Ungar, 2008: p. 314), but where there also exists the explicit 'right not to know' (Chadwick et al., 1997). Ungar described that although efforts to purposively shelter ignorance for moral reasons may be largely doomed to failure, revelations of uncertainties potentially undermining the authority of science become more commonplace as well. Parallel to scientific progress in human medicine, genetics, and biotechnology, public discourses on 'the right not to know' have emerged because of its preventive function (Popitz, 1968) from taking action, for instance, in the birth of a child with possible disorder. Seen from the formal structure of the argument, a 'right not to know' might entail some similarities to that 'liberal' view on ignorance encountered above, insofar it builds on the opportunity of nondiscriminatory effects of social action mechanisms implying nonknowledge. From a sociological perspective, the challenge of the debate lies in the array of implications of that fragile judicial construct for the role of actors, professionals, and the media in societies usually taking a positive stance toward knowledge (Levitt, 1997). Actors, expected to take responsibility for their health and those of their children, in reality do have limited opportunities and resources to exercise choice and be in control of their lives; thus, it is unsurprising that the topic arises "as the technology to predict risks for individuals runs ahead of both available treatments and the human ability to cope with such knowledge" (Levitt, 1997: p. 35).

Based on a broad study on the role of ignorance in various scientific disciplines, and discussing two empirical cases in greater detail, Stefan Böschen et al. (2010: pp. 790f.) identified three different 'epistemic cultures of nonknowledge' as equally valid, rational ways of dealing with nonknowledge: oriented toward control, toward complexity, or toward case-based experience. They characterized the control-oriented approach toward nonknowledge by an epistemic focus on controlling experimental conditions and avoiding disruptive factors, like in molecular biology. In contrast, in ecology they identified a complexity-oriented culture that obtained a high degree of openness toward unanticipated events and uncontrollable, context-sensitive settings. The remaining culture of nonknowledge concentrating on single case-based experience has been developed in professional expertise such as in medical case histories, characterized by a low degree of decontextualization and a tendency to define nonknowledge as problem of an individual expert. The authors suggested that a full recognition of diverse cultures of nonknowledge is required as prerequisite for socially legitimate, robust decision- making under conditions of politicized scientific nonknowledge (Böschen et al., 2010).

While the increasing politicization of scientific nonknowledge is an interesting topic for the sociology of science in its own right, the broader recognition of ignorance both as part of structural conditions of social action and of human knowledge processes enhances social sciences' efforts to cope with what is necessarily implied in advancing the growth of knowledge.

Abstract

As a Catholic priest cum public intellectual, Ivan Illich is best known for his critique of modern industrial society and its institutions, in particular his controversial deschooling proposal set forth in the 1970s. What is often neglected is the significant shift in his subsequent intellectual development, in which Illich turned to cultural history for questioning the modern certainties concerning our practices and needs. On that basis, Illich suggested that the origin of modern culture and its malaises can be traced back to Christianity and its perversion.

Biography

Ivan Illich (1926–2002) is arguably one of the most prominent social critics and cultural historians of the twentieth century. His works are at once influential and controversial, covering a wide range of topics, such as education, medicine, development, gender, literacy, and Christianity. Illich was born in 1926 to a family with maternal Jewish origin in Vienna. In the 1940s, he studied theology and philosophy at the Gregorian University of Rome, and received his doctorate in history from the University of Salzburg. Soon after graduation, Illich was ordained to the Catholic priesthood in Rome. In 1951, Illich moved to the United States, where he became first an assistant pastor in the Puerto Rican migrant community in New York, and, later, the Vice Rector of the Catholic University of Puerto Rico. With the purpose of training young priests for foreign languages and missionary works, Illich cofounded the Center for Intercultural Formation in Cuernavaca, Mexico in 1961, later to be renamed as the *Centro Intercultural de Documentacion* (Center for Intercultural Documentation (CIDOC)) in 1966.

In a series of articles written in this formative period, Illich openly criticized the Roman Catholic Church for its involvement in President Kennedy's development program for Latin America, the so-called 'Alliance for Progress.' In utilizing the CIDOC as an institutional and intellectual platform to reflect upon the Church's role and deflect from Pope XXIII's call to send 10% of the United States clergy to Latin America, Illich was eventually put on interrogation by the Sacred Congregation for the Doctrine of the Faith in Rome. Illich's break with the Vatican was sealed with his renunciation of official priestly services (though not priesthood) in return for its recognition of CIDOC's independence. After the incident, in the 1970s Illich published four spectacularly successful and popular works earning him international fame, namely *Deschooling Society* (1971), *Tools for Conviviality* (1973), *Energy and Equity* (1974), and *Medical Nemesis* (1976).

With the closure of the CIDOC in 1976, Illich's intellectual life entered into a new stage. In the 1980s Illich had largely retreated from the public scene, which signified a general reorientation of his thought from reform to 'renunciation.' Illich's initial plan was to learn oriental languages in India and East Asia, an exposure that he supposed could shed a new light on the cultural assumptions of Western modernity. When such a plan proved to be impractical, Illich returned to Europe and served as a guest lecturer in various universities in Germany and later the United States. With his erudite learning of the Middle Ages, from the 1980s onward, Illich had been publishing studies in Western cultural history. While his later works enjoyed less popularity than those of the 1970s, Illich never failed to gather an intimate circle of friends and students devoted to the same line of intellectual and public inquiry.

Illich died at his friends' home in Bremen, Germany in 2002. True to the spirit of his devastating critiques of schooling and medicalization, Illich never took up any position of full-time professorship in his lifetime. Neither did he seek any extended medical treatment to the cancer like lump growing on his face and staying with him for almost 20 years. In his peculiar fashion, Illich is a priest living up to his faith, though his was a religion of freedom and friendship rather than dogmatism and discipline.

Major Works

In *Celebration of Awareness* (1971), a collection of his early essays in the 1960s, Illich calls for an 'institutional revolution' in which the social arrangements and myths pertaining to modernity are subject to radical questioning and thereby fundamental restructuring. At the outset, Illich is highly critical of United States' program to steer Third World development in its image. According to Illich, the 'war on poverty' in Latin America is no less violent than the war in Vietnam in its zealous, quasimissionary attempt to impose American values and its middle-class ethos upon the world. He criticizes the hypocrisy and condescending ignorance on the part of volunteers, developers, and above all the Roman Catholic Church, whose 'charity' and good intention inadvertently play into the hands of political ideology and, worse still, cause irrevocable damages to the traditional way of life on which the dignity of the poor precariously rests (Illich, 1971: 25). 'Underdevelopment' is thus resulted, which for Illich refers to a state of mind whereby insatiable mass demand for commodities and services are imposed on the otherwise self-sufficient people. Echoing the maxim that the road to hell is paved with good intention, Illich urges the American volunteers to renounce their self-ordained power and duly recognize their inability to 'help' the poor.

Published after his break with the Vatican, *Deschooling Society* (1971) can be regarded as Illich's most influential and groundbreaking work. Based upon his observations in Puerto Rico and Mexico, Illich contends that universal education, in the form of compulsory schooling, had proved to be infeasible and undesirable. Nothing short of 'deschooling' could overcome the inherent bias and fallacy of the existing system. To begin with, Illich considers his assaults on schooling as part of a general critique of modern institutions, in which the human values of health, learning, and autonomy are all rendered into operative goals to be accomplished with resources mobilized (and eventually monopolized) by organized agencies such as hospital, school, and transportation system. For Illich, the growing prevalence of modern institutions and the industrial logic they embody represents a global and universal degradation, as nonmaterial needs come to be manufactured and manipulated as self-perpetuating and ever-rising demands for professional services. But the 'institutionalization of values' is deemed to be self-defeating, as schooling becomes a hindrance to learning, medicine induces illness, and transportation produces traffic jams (cf Illich, 1974).

Illich detects several drawbacks in the field of mass education. First, the disproportionately high cost and low return of the school system makes it *economically infeasible*. Despite rocketing educational expenses, dropout rate remains resilient among the lower class in Latin America and the United States itself. The poor institutional performance, however, justifies ever more costly investment of money and 'good faith' in universal education, thus setting a vicious circle in motion (Illich, 1971: 10). Besides, universal schooling can heighten *social polarization*. With their coerced or willed dependence on educational institutions, the poor must live up to the middle-class standards of learning, consumption, and lifestyle that are deliberately imposed and promulgated by the minority of local elites, new professional classes, and foreign nations (Illich, 1971: 9). Finally, obligatory schooling incurs a generalized *psychological impotence* among the average consumers and particularly the poor, who are deprived of the traditional means of self-education once available in the form of everyday life learning embedded in local community (Illich, 1971: 3).

The school system also exercises a profound impact on the minds of students. School attendance and graded promotion constitute modern 'rites of passage' through which students are calibrated and assigned to occupational, social roles with differential privileges and status honor (Illich, 1971: 44). Together with standardized curriculums and credentials, these rituals convey the mythic belief that the 'innocent children' desperately need to be educated within the institutional settings of the school. Insofar as education is confused with schooling, and progress confused with progression, educationalists can legitimize the necessity and expansion of the school system, whereas the teachers can justify the total submission of students to their moral and professional authority (Illich, 1971: 26–32).

Illich accordingly suggests that the malaises of mass education can be overcome only with deschooling, which refers not to a wholesale elimination of school, but rather its disestablishment. In much the same way as the constitutional disestablishment of the Church in the First Amendment, Illich argues that we should stop allocating public expenditure and granting social privileges to the school achievers (Illich, 1971: 11; see also Illich's foreword to Hern, 1996). In advocating for the abolition of legally enforced school attendance as a prerequisite of employment and citizenship, what Illich has in mind is the spiritual monopoly once assumed by the Church and now being revived by the secular school, which exhibits the same tendency of reducing the values of salvation or education into administrated, profiteering services.

Illich sets forth the 'learning Web' as an alternative to compulsory schooling. The idea is to provide open access to educational and community resources for students and the public to pursue their own (rather than predesignated) learning goals. Credentials are to be replaced by an 'edu-credit card,' with which every citizen can freely utilize reference services and educational tools, consult specialists of various fields, join centre of skill exchanges, and seek out learning partners (Illich, 1971: 78–79). For Illich, these deschooling measures are not only intended to resolve the immediate crisis of compulsory education. His broader purpose is to resurrect what he calls 'Epimethean man,' a man of hindsight who retains hope and faith in the natural goodness of tradition and community, in contrast to the modern 'Promethean man' who attempts to control and manipulate the environment only at one's own peril (Illich, 1971: 105–107).

Illich's critique of modern institutions is further elaborated in *Medical Nemesis* (1976), in which he takes to task the threats to health posed by the medical profession. To this he coins the term *iatrogenesis*, which refers to diseases and epidemics inflicted by the physicians. It occurs when patients are subject to clinical conditions and medical treatments either unnecessary or detrimental to their recovery and health. Illich first demonstrates that the decline of mortality rate in the postwar era was a result of the general improvement of physical environment and hygienic awareness, rather than the effectiveness of doctors and antibiotics (Illich, 1976: 6). Medicalization rather gives rise to *counterproductivity*, the point at which increasing outputs of medical technologies and institutions bring about unwanted side-effects such as expensive but ineffective treatments.

At a deeper level, Illich alerts us to the social pressures exercised by standardized health care and hospitalized treatment, which define any self-healing, dying-at-home, or suffering outside institutionalized sick role as deviance and 'irresponsibility.' When the medical institution appropriates the means of healing and becomes a *radical monopoly*, the majority can have no choice but become patients in order to receive its packaged services (Illich, 1976: 33–35). Medicine eventually becomes a religion, as it seeks to indoctrinate an unquestioned faith in treatment, therapy, and health protection. The myth of medicalization, just like the myth of schooling, legitimizes the expansion of health care and costly investment in high technology by inducing public obsession with diagnosis and preventive measures (Illich, 1976: 106).

Hence for Illich, the dominance of medical profession reinforces iatrogenesis as it destroys culturally specific ways of coping with suffering and death. While medicine purports to 'kill' or eliminate pain, vernacular culture inculcates an 'art of suffering' with which a person can live through the necessity of illness and death in grace and dignity. Insofar as pain and death are reduced from cultural performances of the body into mere

clinical symptoms, these episodes of the human condition are devoid of personal meaning and virtue, and become utterly intolerable and meaningless to the spoiled consumers (Illich, 1976: 129–130). In line with his renunciation of the Promethean man in *Deschooling Society*, Illich asserts that the overall outcome of iatrogenesis is 'medical nemesis,' that is, divine vengeance on human beings' 'hubris' or presumption to become gods in their own right. Instead of top-down reform by the medical profession, medical nemesis can be dispelled only with a reversal of heteronomous professional monopoly and resumption of self-care among laypersons.

Alongside his critiques of educational and medical institutions, Illich outlines his ideal society in *Tools for Conviviality* (1973). For Illich, 'conviviality' is the exact opposite of industrial productivity. It connotes the autonomous, creative intercourse of persons with each other and with their environment (Illich, 1973: 11). What is going to supersede the industrial age is a 'convivial society' in which all social members can enjoy equal, open access to physical means and institutional arrangements that enable and facilitate their activities. For Illich, the task is to regain democratic control over these 'tools' from technical experts, such that they can be put in the service of genuine human needs, creative joy, and individual freedom. In place of technocratic decisions, we shall need to revive deliberative procedures through which autonomous individuals can engage in the political process of resolving differences and negotiating the proper usage and reasonable scope of social tools.

Starting from the 1980s, Illich's intellectual development had been undergoing a radical reorientation. *Gender* (1983) can be taken as a transitional work in this period, where Illich sets forth the unconventional argument that modern industrial society can be understood in terms of the transition from the age of gender to that of sex. For Illich, 'gender' and 'sex' are crucial, since they represent two basic principles of social organization and modes of social existence. In the first place, 'gender' represents the reign of *duality* in vernacular culture, which consists in an unequal albeit complementary relationship that permeates and distinguishes "places, times, tools, tasks, forms of speech, gestures, and perceptions that are associated with men from those associated with women" (Illich, 1983: 3). Every specific practice, perception, and position is thus 'gendered' or marked in definite, proportional relationships within the Great Chain of Being. Being cosmos and social milieu at once, gender connotes not so much inequality than hierarchy. It constitutes a 'commons' that defines the general, proper limits of concerted actions and shared activities on the part of both men and women, who accordingly have recognizable (albeit differential) claims to their respective shares in the overall subsistence of a kin-based community.

In contrast to vernacular gender, 'sex' is a regime of economic *scarcity* at once equalizing and polarizing. From the late eighteenth century onward, common characteristics are attributed to all human beings *in abstraction from* their dual relatedness in gendered traditional culture (Illich, 1983: 4). The notion of universal humanity is essentially genderless or 'unisex,' as biological and sexual constitutions become exogenous to the definition of every single individual. On the basis of this cultural and ontological assumption, both male and female are supposed to exhibit the same set of abstract human needs, and are accordingly subject to the same life order and work requirements. From this 'genderless individualism' follows the economic theory of scarcity and competition, which legitimizes women's equal opportunity *and* disadvantageous position vis-à-vis the men (Illich, 1983: 9–10).

Insofar as culturally embedded gender is replaced by disembedded economic neuter, the modern institutions of industrial production and universal education are set into motion, both of which operating under the assumption of scarcity and to the effect of social polarization. In contrast to the loosely regulated social milieu of gender, the hidden injuries of women, the poor and other disadvantaged categories are without limits under the modern regime of sex (Illich, 1983: 11–13). Illich thus concludes that no remedies can be provided to sexual and social exploitation as long as one stay within the formally free but substantively repressive order of modern institutions and languages. The common parlance of 'role' and 'need' in contemporary culture is imbued with a conception of society bifurcating in conformity and deviance from predefined rules or standards. On the other hand, the gender metaphors in vernacular tradition outline the general limits or 'necessities' of action, within which social agents (*qua* persons and bodies) can enjoy the liberty to pursue proper goals, cultivate personal virtues, and engage in the concrete, convivial life of their community.

In hindsight, it is perhaps not surprising that *Gender* provoked fierce criticisms from mainstream feminists like Arlie Hochschild (Bruno-Jofre and Zaldivar, 2012: 581). In fact, Illich composed the book with the incommensurability of gender and sex, or the principles of proportionality and equality in mind. Instead of the feminists' (and modernists') preoccupation with individuality and universality, what Illich advocated for was a recovery of the commons and its vernacular virtues. In this light, the controversy had partly to do with Illich's previous role of social critic, which still lingered in the academic public and obscured his repositioning as cultural historian. Instead of promising the redemption of convivial *tools* and *institutions*, Illich's new task was to question those 'modern certainties' permeating our practices, *discourses* and *senses*, and thereby to reclaim the cultural alternatives long buried in our passage to modernity.

The intellectual reorientation in *Gender*, together with other exploratory works such as *H_2O and the Water of Forgetfulness* (1985) and *ABC: The Alphabetization of the Popular Mind* (1988), eventually leads Illich to fundamental reconsiderations of his longstanding critiques of education and medicine. In his foreword to a volume (Hern, 1996) dedicated to reexamining the deschooling thesis, Illich confesses that he was 'barking up the wrong tree.' For Illich, it proves to be futile to call for education reform by disestablishing school, since its critical potential can be readily assimilated by educationalists in the institutionalization of alternative and lifelong learning programs. While Illich pointed his finger at the inadequacy of school system as means, institutions or tools, he never questioned the desirability of education as an end, need, or value. Hence his early critique of schooling still borne the modernist assumption that 'educational needs' are a given of human nature. Instead of the social effects of schooling, the right question to ponder should be the *ideology* of educational needs.

What Illich wants to problematize is the historicity of *homo educandus*, whose imputed needs laid down the basis of the doctrine of scarcity as applied to educational means and values, against which the school system and its professionally managed alternatives are legitimized.

From where did the need to be socialized, educated, and examined arise in the first place? Illich ventures to seek an answer from the history of reading and literacy. In his highly original work, *In the Vineyard of the Text* (1993), Illich argues that the practice of reading had undergone a significant change in the twelfth century. Prior to that period, the monks used to read biblical texts in an uninterrupted fashion, that is, by reading aloud and following through the unbroken string of words from beginning to end. When the page was invented in the High Middle Ages, spaces were inserted between letters and chapters, such that the reader no longer had to wander around the 'vineyard' but could rather distance oneself from the text. The modern practice of reading thus generates a corresponding inner text or space on the part of individual subject, a 'conscience' that is composed of words and deeds and constitutes a life record susceptible to examination and judgment by God, the Church, and the School.

Illich (1996) then sets out to question the modern certainties of 'life,' 'health,' and 'death' as the ideological underpinnings of medical profession. Alongside the rise of alternative education, Illich proposes that we are entering into a new era of relentless medicalization, in which the physicians not only cure diseases but progressively take up the management of life from womb to tomb. But the widening and deepening of medical system would not be possible without a corresponding 'sacralization of life,' a myth that reifies survival and physical health as something we bear the indubitable responsibility to preserve at all costs (Illich, 1996: 18). According to Illich, the modern Western notion of life has its deepest root in Christianity, which originally conceives of it as a gratuitous gift from Jesus, a revelation that life always means *being a person*. With the subsequent death of nature in scientific revolution and the rise of possessive individualism in capitalist economy, however, 'life' (along with 'health') comes to be redefined as a substance to be maintained, manipulated, and managed (Illich, 1996: 19).

According to the later Illich, the only way out of this self-incurred predicament of the human condition is *askesis* or renunciation, which consists in the suspension of beliefs and attachments to the modern certainties and values of life, health, and death, and with them the responsibility and 'right' to health care (Illich, 1996: 26). As an epistemological guideline and ethical maxim, renunciation is to restore our genuine liberty by duly recognizing the *existential* limits of our body and life, within which we can deliberately cultivate the arts of suffering, dying and loving, and in this way live out our personal meanings. From this perspective, conviviality acquires a renewed, quasi-Christian meaning of catering to our neighbors' genuine needs and lives.

The central significance of 'person' and its root in Christianity receives final exposition in Illich's (2005) last conversations with David Cayley. There Illich sums up his lifelong investigations into modern society and its institutions with the old Latin phrase, *corruptio optimi quae est pessima*, 'the corruption of the best is the worst.' By this Illich proposes that modernity can be best understood in relation to the cultural legacies of Christianity, not as its realization or antithesis but rather *perversion*. Here Illich refers to the story of the good Samaritan told by Jesus in answering the question, "who is my neighbor?" According to Illich's reading, the story conveys the core Christian message that the neighbor can be anyone with whom we voluntarily relate. In this light, the Gospel reveals our untrammeled freedom to love and to see the Incarnation of God in the bodily presence of *this* stranger we happen to encounter. To engage in a voluntary, concrete, and personal relationship with others, and thereby with Jesus, is a call rather than an obligation, since for Christians love always stands above law, custom, language, and any indeed rule or code. Accordingly Illich stresses that 'sin' in its original sense, entails the denial of this personal call to love one's neighbor, rather than the violation of any universal law or moral rule (Illich, 2005: 189).

The early Christian community exemplifies a being-togetherness that fulfills the calling of universal albeit corporeal, interpersonal love. Apart from the Eucharist in which Christians eat, drink, and share the mystical body of Jesus, Illich tells us that *conspiratio* or 'respiring together' was once practiced among the apostles, a ritual of mouth-to-mouth kissing in which the bodies were thereby tied together and suffused with the Holy Spirit (Illich, 2005: 85). The profound corporeality and mutuality of the early Christian community, which for Illich constituted a commons par excellence, was eventually lost with the establishment of the Church, which purported to convert love and charity from personal freedom and virtues to institutionalized rules and values. With the building of parish and the writing of conscience inaugurated by the medieval church around the twelfth century, sin was 'criminalized' as it became an offense against moral duty instead of an incapacity to answer personal call (Illich, 2005: 92). Virtue, friendship, and the good were accordingly transfigured into categorical imperative and moral responsibility, a betrayal of Jesus' promise to free us from the law. The moment of perversion in Christianity occurred when the established Church (and later the school and the clinic) assumed the role of inculcating and sanctioning the spiritual needs of its flock. Illich's cultural history of modernity thus suggests that the deepest source of its evils has to be sought in the process of institutionalization that turns Christianity into its exact opposite, the blasphemy of life that is the 'Anti-Christ.'

Impacts

Among his manifold contributions to the critical interrogations on modern industrial society, Illich's impact has been most strongly felt in the field of education. Shortly after the publication of *Deschooling Society*, educationalists of all stripes issued their critical responses and largely polarized judgments on Illich's position. After a brief period of serious attention amid the crisis of the modern school system in the 1970s, Illich's challenges were soon assimilated into the mainstream under the name of 'alternative education' (Botsford, 1993). Into the 1990s, however, Illich's ideas had begun to regain influences among scholars directly involved in the deschooling movement (Hern, 1996), and those working in the closely related

fields of critical pedagogy (Finkel and Arney, 1995) and adult education (Finger and Asún, 2001). More recently, attempts are made to reconsider Illich's educational thought in the context of his overall intellectual development, thus signaling a new stage of Illich scholarship (Zaldivar, 2011; Bruno-Jofre and Zaldivar, 2012).

In much the same fashion as deschooling, Illich's notion of 'medical nemesis' elicited an extended rejoinder (Horrobin, 1978) that consisted in a largely positive review of Illich's general position, together with a careful assessment of some of his empirical claims and specific contentions. A general revival of interest in Illich is in place as his pioneering critique of medicalization is subject to contemporary reappraisal in light of recent medical advances (Bunker, 2001). Illich's wide-ranging explorations in other problem areas are likewise taken up by scholars and practitioners, such as postdevelopment studies (Rahnema, 1997), peace studies (Kaller-Diestrich, 2011), environmental movement (Mancini, 1998), community work (Schwartz, 1997), and design and architecture (Mitcham, 2003).

Symposiums and conferences were held to pursue certain aspects of Illich's thought, including a symposium on law (Levi, 2012) and a conference on contemporary commons movement (Bollier, 2013). No less significant was the publication of an anthology of personal recollections and cultural–historical investigations in the spirit of Illich (Hoinacki and Mitcham, 2002). The founding of the *International Journal of Illich Studies*, in 2009, furnishes a major site of online publication and open access to secondary works on Illich. Finally, while the religious and philosophical dimension of Illich's social thought had received scant attention in the earlier literature, some commentators begin to draw our attention to the theological background in Illich's works (Inchausti, 2005; Bruno-Jofre and Zaldivar, 2012).

In conclusion, Illich's major contribution is to trace the origins of modern evils in institutional counterproductivity and the perversion of Christian ethics. His works have come full circle from denouncing the good intention of zealous missionaries to revealing the corruption of religious visions. At any rate, Illich's critiques cannot be conveniently dismissed as naive antimodernism. At least for the early Illich, industrial tools (and postindustrial one such as the Internet) can be reinvented in politics and contribute to the making of post-traditional, convivial society. Despite certain affinity of his later works with the postmodernists, in particular the exposé of modernity as a discursive, disciplinary regime à la Michel Foucault, as a man of faith Illich would positively recommend interpersonal, unalienated love as an antidote to the corrosive will to power, which should be radically renounced rather than affirmed in any Nietzschean fashion. In this regard, Illich seems to urge us to go beyond the modern polarities of discipline and resistance, by *choosing* to live in the small but beautiful world of friendship and proportionality. While his final commentaries on Christianity and Western culture remain underdeveloped, Illich's profound insights can open promising lines of intellectual inquiry and political intervention on modernity as a distinct civilizational and institutional order.

Abstract

This article provides a sociological analysis of functional illiteracy, a problem widespread in the less developed countries, but is invisibly present in the developed countries as well. After clarifying the conceptual basket of illiteracy, the article discusses trends and patterns in functional illiteracy, and concludes with a discussion on the social context in which functional illiteracy needs to be understood.

The noun *illiteracy* (or analphabetism) is a derivative of the noun *illiterate*, which refers to a person who is unable to read or write, other derivatives being the noun *illiterateness*, adjective *illiterate*, and adverb *illiterately*. Thus, lexicologically, illiteracy, in all its inflections, is defined as the antonym of *literacy*, the ability to read and write. In reality, however, between absolute illiteracy and total literacy, different levels of abilities may be distinguished, including *quasi-literacy* and *functional illiteracy*. Empirical evidence shows that the majority of adults, both men and women, in highly developed as well as the less developed countries rank somewhere among these in-between levels. The situation appears to depend mainly on the fact that the way of life and work for large numbers of the population, even in the developed countries, does not require more than rudimentary literacy skills.

The nature and implications of being functionally illiterate, that is, lacking the literacy skills necessary for coping with most jobs and daily situations, is not the same either across different countries or across different strata or categories of the population within a given country. It is well known that lower social strata are more vulnerable to the risks of functional illiteracy, although the rest of society is not immune. In some societies, historically, sections of the population, for example, indigent castes in India and isolated communities in China, were prevented from acquiring literacy skills, which were the exclusive privilege of the literati castes and communities. Even in the literati castes and communities, literacy was the privilege of men, a fact that explains the continued gender skewedness of literacy rates unfavorable for women.

Many tribal and village communities in Africa and Asia were predominantly oral and many linguistic communities did not have a script in which to write their language with. Only when these communities became integrated with the mainstream literate communities or started interacting with them did the need for acquiring reading and writing skills arise. For many such communities, acquiring literacy skills meant acquiring a new language, too. In some cases, they adopted the script of an alien language, most often the language of their colonizers or of the societies into which they came to be integrated. Obviously, the sections of the population that had least resistance to literacy or understood its benefits as a social capital had a lead advantage in such transition.

Furthermore, being functionally literate in one language, often the mother tongue, even if it has a script, is not enough. In multilingual societies, not all the languages enjoy the same functional status. One or two languages may be given the status of the national or official language, which thereby become the dominant functional language of the society. So, in which language one is (il)literate determines how effectively he/she can engage himself/herself in the wider economic and political life of the society. Thus, in multilingual societies, (il)literacy has different connotation and implications, as compared to a monolingual society. Often, regional, religious, and cultural factors prevent individuals from acquiring literacy in a language other their own.

Definition of literacy, and thereby what it means to be illiterate, has also been changing. Today, being fully literate means not just the ability to read and write one's own name; it refers to the ability to read for information and interest, write legibly and coherently, and reflect about the written word. It encompasses the complex set of abilities to understand and use all the symbol systems relevant to a particular community. Thus, in the era of information technology, the concept could be expanded to include the multimedia and electronic text, in addition to conventional alphabetic and numeric systems. These abilities vary across social and cultural contexts, according to need and demand. Thus, both the meaning and the implications of illiteracy is more an empirical issue rather being merely a conceptual issue.

Some experts are of the opinion that literacy is juxtaposed to orality (see Olson and Torrance, 1991). Orality characterizes "societies that have relied on oral communication without the use of writing and are against privileging literacy over orality"; it seeks "to identify a given type of language used in oral communication … and a given type of consciousness, which is supposed to be created by orality or expressible in orality" (Havelock, 1991: 11). While orality and literacy are "sharpened and focused against each other" in many societies in the less developed countries, they are "still interwoven" in the developed world. The recognition of the importance of orality challenges the privileging of literacy and theorizing about the advantage of literacy (Pattanayak, 1991: 105).

Experts on literacy are not convinced that literacy affects intellectual and social change in any straightforward fashion. As Olson, Hildyard, and Torrance observe, "it is misleading to think of literacy in terms of consequences. What matters is what people do with literacy, not what literacy does to people" (1985: 14). Nevertheless, throughout the world, policy makers

have grouped illiteracy with poverty, malnutrition, and lack of education and health care. Total literacy is a cherished value and an avowed objective of many a development plan, especially in the less developed countries many of which have been struggling to achieve it.

Countries that have successfully addressed the scourge of mass illiteracy have done so in the campaign mode. Most of such campaigns since the beginning of the twentieth century have been undertaken as part of an ongoing, larger structural or socioeconomic transformation. The campaigns in the former Soviet Union, the People's Republic of China, the Socialist Republic of Vietnam, and Cuba are cases in point. A more recent illustration is that of India's mass literacy campaigns (see Athreya and Chunkath, 1996). What distinguishes these campaigns from earlier educational movements (in Germany, Scotland, and Sweden, for instance) is their short, time-bound period and the sense of urgency that briefed them.

Part of the great success achieved by the twentieth century campaigns for eradicating mass illiteracy, as in former Soviet Union and Peoples' Republic of China, can be partly attributed to the more effective centralization of political power in these countries, as also the revolution in the technologies necessary for spreading literacy. However, besides the constraints of democracy and federalism and the politics of regionalism, as in the case of India, the existence of complex alphabetical systems (with elaborate symbols) of some languages has been a stumbling block. Even otherwise, in contexts where minimal literacy skills are sufficient, functional illiterates generally cope without much difficulty.

Illiteracy Statistics

Thirty-nine of the 198 countries for which data are available have no illiteracy or less than 1% of illiteracy and, in all, 79 countries have literacy rate of more than 95%. Besides most of the Western and Eastern European countries, these include Australia, Canada, Israel, Japan, New Zealand, the United States or, for instance, Argentina, Barbados, Chile, Cuba, Mongolia, North Korea, the Philippines, Qatar, South Korea, Taiwan, Tajikistan, Trinidad and Tobago, and Uruguay. Leaving out these, all other countries lag somewhat or further behind: 62 countries have more than the world average of illiteracy (16%); in 13 countries, more than 50% of the population is illiterate, with Burkina Faso having the highest percentage (78%) of illiteracy.

Over the twentieth century, the absolute number of completely illiterate adults increased in the less developed countries, mostly due to population growth. In terms of percentages, however, adult illiteracy declined everywhere; the world illiteracy halved between 1970 and 2005. Table 1 illustrates this point as regards six countries typical of different degrees of economic development (Girod, 2001: 7182).

The official statistics of illiteracy among adults in many countries are not precise and reliable. They give little or no information about the real literacy capacities of the adults who are not counted as completely illiterate. Not all countries collect literacy statistics regularly and this imposes restrictions on comparison, across countries or within a country over time.

Table 1 Percentage of illiterate adults from 1900 to 2010 in six countries (UNESCO estimates and national statistics)

	1900	*1950*	*1970*	*1990*	*2010*
USA	11	3	1	–	1
Italy	50	14	6	–	1
Mexico	78	43	25	12	7
Brazil	65	51	32	–	10
India	94	81	66	52	26
Mali	–	–	94	–	69

Functional Illiteracy

The less developed countries are aware of the extent of functional illiteracy of their adult population, and they are all struggling to improve the literacy levels. In developed countries, on the other hand, thanks to decades of universal compulsory free education, the problem of functional illiteracy was thought to be a concern of the past. But many of these countries have been rudely shaken by the findings of empirical research that functional illiteracy was frequent in modern societies, although the problem is not as serious as in the less developed countries. The first international survey of literacy skills was conducted in 1994–2005 under the auspices of the Organization of Economic Co-operation and Development (OECD, 1995, 1997). The survey covered 12 countries, 7 in Western Europe, and Australia, Canada, New Zealand, Poland, and the United States. A uniform set of reading, writing, and arithmetic exercises typically required in daily life and work was administered to evaluate the literacy level of adults aged 16 to 65 years. This survey revealed interesting facts about the distribution of the adult population of the developed countries by literacy levels at the turn of the twentieth century (see Table 2) (Girod, 2001: 7182).

The four categories of Table 2, which excludes immigrants, correspond to the following levels of literacy (Girod, 2001: 7183):

1. *Good:* Ability to at least understand newspapers and nontechnical articles written for the general public, write a simple letter, perform elementary arithmetic, read a road map, etc. These skills correspond roughly to the kind of reading, writing, and arithmetic abilities that compulsory schooling tries to instill.
2. *Mediocre*: Between nearly good and nearly low levels.

Table 2 Percentages of adult population aged 16–65 years (born in the country) by literary levels. Three examples: Germany, Sweden, and the United States in 1994

Literacy levels	*Germany*	*Sweden*	*United States*
Good	19	36	23
Mediocre	41	40	34
Low	31	19	27
Quasi-illiteracy	9	5	16
Total (%)	100	100	100

Organization of Economic Co-operation and Development (OECD), 1995. Literacy, Economy and Society. OECD, Paris.

3. *Low*: At most can understand parts of short, very easy articles; complete a basic application for employment; interpret a pay stub, etc.
4. *Quasi-illiteracy*: At most can understand or write isolated phrases, add or subtract small numbers; often can only understand or write isolated words and numbers. Exceptionally, complete illiteracy.

Sweden ranked top in the survey, although its adults found to have 'good' level of literacy did not make up the majority. In all other countries surveyed, the percentage of adults in the 'good' level of literacy was lower. In Sweden, approximately one in four adults was found to be functionally illiterate (categories (3) and (4)). In the remaining 11 countries, the rate of functional illiteracy was much higher. In the absence of comparable data, landmarks of change are extremely difficult to identify (Girod, 2001: 7183).

Coulombe et al. (2004) derive synthetic time-series over the 1960–95 period on the literacy level of labor market entrants from the age structure of the 1994 International Adult Literacy Survey. They then use these data as a measure of investment in education in a panel data analysis of cross-country growth for 14 OECD countries, namely, Belgium, Canada, Denmark, Finland, Germany, Ireland, Italy, Netherlands, New Zealand, Norway, Sweden, Switzerland, the United Kingdom, and the United States. Their results show that, overall, human capital indicators based on literacy scores have a positive and significant effect on the transitory growth path, and on the long-run levels of gross domestic product per capita and labor productivity. Thus, in contrast to most previous findings, human capital accumulation is found to matter for the long-run well-being of developed nations.

Social Contexts and Illiteracy

Sociological analyses of the reasons for high rates of complete or functional adult illiteracy in less developed countries provide valuable insights. First, a significant proportion of the children does not enroll in or attend primary school at all. The proportion of such cases is decreasing due to the increase in the number of schools and governmental efforts at canvassing enrollment in these schools. Also, more families are becoming aware of the possibility of sending their children to school. However, most families lack the cultural capital to appreciate the importance of education per se, and this is reflected in the poor motivation among the children. Not surprisingly, the children enrolled in the schools drop out; it is estimated that approximately one-fifth of the children on average drop out of the first year of primary school and still many before the end of the fourth year (Girod, 2001: 7183).

Sociologists attribute the high dropout rates in less developed countries to the lack of fit between schooling and the skills necessary for the milieu in which these children live and grow. Their parents tend to think that their children are wasting time at school. In many instances, they would prefer to have the children around for helping with their own job or working independently to supplement the family income.

With jobless growth being a characteristic of the less developed countries during the last few decades, there has been what one could call *education inflation*. With ever more people available with educational credentials, employers tend to escalate the educational requirements for jobs that people with primary school education did earlier. Under these circumstances, primary school education has lost its significance in the job market. For families living on the margins of poverty, the opportunity cost of sending their children to even primary schools would be high. Primary school carries no immediate upward socioeconomic mobility significance to such families (Tanguiane, 1990).

As noted earlier, many adults in less developed countries belong to social strata where illiteracy is the rule and almost all communication is oral. In such cases, the skills acquired during the few years of schooling or through adult education or mass literacy campaigns are never or rarely used. In most cases, they deteriorate or disappear altogether. Thus, many a new literate in less developed countries lapse back into complete illiteracy or close to it (Girod, 2001: 7183).

The problem of functional illiteracy, however, is not unique to the less developed countries. Although not as striking, the presence of a large number of functionally illiterate people in the developed countries, including in Sweden, the United States, and Germany, revealed by the international surveys (see **Table 2**) points to the invisibility of functional literacy in most modern nations. With the possibility of a section of the adult population, even in developed countries, slipping into functional illiteracy, there hardly appears any scope for complacency.

What is serious about the quasi-illiterate and low-literate adults is that they are generally not themselves even aware of having reading, writing, and computing problems. Very often, they do not admit to having poor literacy skills. If the limited literacy abilities of a significant portion of the adult population prevent them from coping normally at work, at home, in a market-place, on the road, etc., then they would constantly make mistakes and have difficulties in the world around them. However, this is not the case, for reasons identified by Girod (2001: 7184).

1. Most quasi- and low-literate adults are capable of performing very simple or at least rudimentary literacy tasks like reading and writing, recognizing numbers, and making simple arithmetic calculations.
2. Not all or even most members of the society need possess sophisticated reading, writing, and arithmetic skills. Routine housework, many jobs, and leisure-time activities can be performed with the levels of literacy skills possessed by quasi-illiterates or low-literates. More and more push-button or touch-screen technological devices are designed keeping in mind lower levels of literacy skills.
3. Reading for pleasure is no more a habit among most adults; writing even less so. With television becoming a popular medium of information and entertainment, a large percentage of adults have ceased or almost so to read books. Electronic calculators and computing devices have relegated paper and pencil to the margins of household stationery.
4. If reading, writing, or computing is useful or necessary, it is always easy to find help at home or at work.

5. The prestige that literacy once bestowed when the society was predominantly illiterate has waned with the spread of literacy.

Girod's analysis reveals that notwithstanding the difference between the less and most developed countries, the basic mechanisms at work as regards literacy and illiteracy are the same. They influence individual motivations and achievements both at a young age and later in life. "These mechanisms, on the whole, form rather clear tendencies towards an approximate equilibrium between, on the one hand, the common subjective and objective needs of the individual's social and occupational milieu and, on the other hand, their reading, writing and computing capacities" (Girod, 2001: 7184).

To reiterate Girod's conclusion, "As long as they cope with the limited demands inherent in their roles at work and in society, with respect to reading, writing, and computing, functional illiterates are generally not inclined to improve their literacy skills" (2001: 7184–7185). Here lies the formidable obstacle to the success of adult education programs and mass literacy campaigns.

Illness and Dyadic Coping

Guy Bodenmann, University of Zurich, Zürich, Switzerland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

While coping was viewed as an individual process for a long time, dyadic coping is an attempt to conceptualize stress and coping as an interpersonal phenomenon. This means that a stressor always affects both partners and thus represents a shared problem. On the other hand, it also means that couples have resources to cope together against these adversities. In the context of illness this perspective invites to consider both partners as part of the trouble ('we-disease') as both, the ill one and the other, are suffering from the situation. Both are, however, also capable to mutually engage in joint efforts to deal with the illness (joint coping) and thus make us of their synergies. More recent studies illustrate that dyadic coping plays an important role in understanding relationship functioning and well-being of patients in close relationships.

Within the last two decades, the individual-oriented perspective of viewing illness as a personal issue has been enlarged by considering the social context. Thus physical and psychological disorders have no longer been studied by excluding variables such as social support, family resources, and relationship functioning. The bio-psycho-social model of illness became more recognized and accepted and scholars as well as practitioners are more aware that physical as well as psychological disorders are embedded in social context (Revenson and Lepore, 2012). An increasing amount of studies supports the strong association between relationship functioning and psychological (Whisman and Uebelacker, 2009) as well as somatic well-being (Robles and Kiecolt-Glaser, 2003). The interplay between close relationship functioning and health (Proulx et al., 2007) is well established (*see* Japan: Sociocultural Aspects). Among relationship variables relevant for health issue, (1) critical, hostile or over-protective attitudes of the partner (see concept of expressed emotion, Hooley, 2007), and (2) negative or ambivalent interaction behavior (Saxbe and Repetti, 2010) or support processes (Uchino, 2006) are discussed. Since almost 20 years, the notion of dyadic coping became an increasingly important variable within the context of health. Several theoretical approaches of dyadic coping or social support in close relationships have been proposed and a great deal of studies addressed this concept in the context of well-being.

Theoretical Concepts of Dyadic Coping

A dyadically enlarged perspective of coping in couples has been suggested by a number of theorists and researchers proposing to define coping in dyads as an interpersonal process involving both partners yielding to different conceptualizations of dyadic coping as (1) an *effort to establish and maintain close relationships* (e.g., Coyne and Smith, 1991; DeLongis and O'Brien, 1990), (2) the *congruence of individual coping efforts within both partners* (Revenson, 1994), and (3) an *interpersonal coping process* by involving both partners in order to reduce problem- and emotion-focused stress (Berg and Upchurch, 2007; Bodenmann, 1995, 2005).

Dyadic Coping as Relationship-Focused Coping

The theorists of the first approach assume that partners do not only have to engage in problem- or emotion-focused coping facing an important chronic or life threatening illness but that they also need to manage the mutual emotional needs of both partners and that they have to deal with the impact of the illness on the close relationship as well. Thus Coyne and Smith (1991) proposed to introduce *relationship-focused coping* as a third coping category, which includes the partners' efforts to reduce stress in the partner and to guarantee his or her physical and psychological well-being. The authors suggested three main strategies: (1) *active engagement* (involving the partner in constructive problem solving, problem-oriented discussions, and helping to explore the feelings of the partner), (2) *protective buffering* (hiding concerns, denying worries, avoiding disagreements), and (3) *overprotectiveness* (dominant, aggressive or submissive strategies to avoid strong emotional involvement).

DeLongis and O'Brien (1990) proposed a somewhat similar approach by focusing on dyadic efforts to maintain the quality of the relationship also in situations of high stressful encounters (e.g., the dementia of one partner). They assume that relationship-focused coping preserves and enhances social relationships (or disrupt dysfunctional relationships) and emphasize the importance of *empathic coping* (affective awareness of the partner's problem and communicating him/her this understanding in an appropriate manner) within this form of coping.

Dyadic Coping as Coping Congruence between the Partners

Theorists referring to dyadic coping as *coping congruence* or *discrepancy* between the partners argue that the compatibility of problem- and emotion-focused coping strategies within both partners may be predictive of marital adjustment. This approach emphasizes the use of similar or complementary coping strategies of the partners facing a common stress event assuming that a high congruence on the applied

individual coping strategies of both partners may be functional, especially with respect to emotion-focused and dissimilar to problem-focused coping (Revenson, 1994).

Dyadic Coping as an Interpersonal Process

In the conceptualization of dyadic coping as an interpersonal process (Bodenmann, 1995, 2005), a systemic transactional model (STM) of stress and coping in close relationships is proposed, defining dyadic coping as an interplay of stress signals of one partner and coping reactions of the other partner to these signals.

Depending upon the stress event at stake, in dyadic coping the stress management resources of both partners are activated in order to maintain or restore a state of homeostasis among both partners as individuals, within the couple as a unit and in regard to other social partners, since it is assumed that one partner's well-being and satisfaction highly depends upon the other's well-being and satisfaction as well as social integration in their social environment. Thus, both partners are motivated (if they are willing to invest in the relationship) to help one another deal with stressful encounters. According to the profile of the situation, the individual and dyadic appraisals, causal attributions and goals, *common*, *supportive*, or *delegated dyadic coping* can be differentiated. These different forms of dyadic coping can be problem-centered or emotion-centered and may be either positive or negative (hostile, ambivalent, superficial) in nature. Whereas in *common or joint dyadic coping* both partners participate in the coping process more or less symmetrically in order to handle a problem-focused or emotion-focused issue relevant to the dyad (by means of joint problem solving, equal division of tasks, joint information seeking, mutual solidarity, joint relaxation exercises, common religious activities), *supportive dyadic coping* is provided by one partner in an attempt to support the other partner who is generally or presently less equipped with the coping resources required to achieve the maintenance or restoration of an adaptive state (by concrete help with daily tasks, supplying relevant information, practical advice, interest to his/her problems, helping the partner to reframe the situation, helping the partner to relax and slow down, manifesting belief in the partner's capabilities, expressing solidarity with the partner). In *delegated dyadic coping*, one partner takes over certain tasks and duties of the other in an effort to reduce the stress experienced by the partner (e.g., one partner does the shopping instead of the other in order to contribute to reducing the partner's stress). According to STM each form of dyadic coping is displayed in accordance to (1) which partner (or both) is primarily concerned by the stress situation, (2) who has coping resources, and (3) what appraisals and goals are at stake. Bodenmann et al. (2011) showed that STM has a significantly higher power than the congruence approach in predicting relationship quality and well-being.

Dyadic Coping and Physical Illness

Although the concept of dyadic coping is relatively recent, an increasing amount of empirical studies support its relevance in couples' and health research. Dyadic coping has been revealed to be a significant and important predictor of relationship functioning and lower stress experience. As relationship functioning is a significant and important predictor of psychological and physical well-being, the assumption is that dyadic coping contributes directly to a better relationship functioning and by this mean to a better well-being (Badr et al., 2010; Bodenmann et al., 2011). The association between dyadic coping and relationship quality is strong and robust (Bodenmann et al., 2011, 2006; Herzberg, 2013; Papp and Witt, 2010).

Findings not only suggest concurrent but also longitudinal associations between dyadic coping and relationship satisfaction (Bodenmann et al., 2006) or divorce (Bodenmann and Cina, 2006). Furthermore, dyadic coping buffers negative effects of stress on aggression in couples (Bodenmann et al., 2010). All these effects assume that dyadic coping exerts a positive effect on well-being by improving relationship satisfaction, which is one key factor in understanding the health of both partners (Robles and Kiecolt-Glaser, 2003). Thus, more indirect effects are expectable. Numerous studies, however, also support positive direct associations between dyadic coping and adjustment in the context of chronic illness (Acitelli and Badr, 2005; Badr et al., 2010; Berg and Upchurch, 2007; Berg et al., 2008; Coyne et al., 2001; Kayser, 2005; Kuijer et al., 2000; Hagedoorn et al., 2008; Manne et al., 2005; Rohrbaugh et al., 2002). Bodenmann et al. (2011) also reported direct associations between dyadic coping and physical well-being.

In a study by Jenewein et al. (2011) in the context of Chronic obstructive pulmonary disease (COPD), low positive and high negative dyadic coping were associated with poorer quality of life and higher psychological distress among patients and their partners. Delegated coping (assistance with daily tasks) was significantly higher among partners. High delegated partner coping (frequent provision of support provided by the partner) and low delegated dyadic coping was associated with poorer quality of life for both patient and partner. COPD patients suffering from depression were supported by their partner considerably more often and attributed deficits in dyadic coping primarily to themselves, while partners with higher scores of depression assessed both their own dyadic coping and that of the patient more negatively.

A study by Whisman and Sbarra (2012) further shows that even wound healing (measured by the biomarker cytokine (IL-6) is positively related to partners' support, especially in women. Uchino (2006) reports various cardiovascular, neuro-endocrine, and immune functional effects of partners' support.

Dyadic Coping and Mental Disorders

Nowadays, only a few studies have investigated dyadic coping in couples with mental disorders. Nevertheless, there is some empirical evidence for the importance of dyadic coping also in this context. Dyadic coping is significantly (negatively) related to psychological disorders such as depression (Bodenmann et al., 2004), compulsive obsessive disorders in couples (Foerster, 2009), or anxiety disorders in couples (Forberg, 2010). Studies show that negative dyadic coping is usually higher in couples where one partner is diagnosed with a psychological disorder.

We-Disease as a New Definition of Disorders

Within a bio-psycho-social view of disorders, the concept of 'we-disease' is particularly noteworthy (Badr et al., 2010; Kayser et al., 2007). 'We-disease' offers a new perspective on support and coping processes in couples dealing with psychological and physical disorders. In the concept of 'we-disease' couples are considered to face the illness as a shared 'we-event' and a 'we-experience' rather than an individual problem of one partner requiring support from the other. This means that the illness of one partner is no longer viewed as his/her illness but is appraised as 'a shared problem' as it concerns both partners as a whole. From this perspective, since the illness affects both partners they may have a vital interest to overcome the illness together since health impacts both. The concept of 'we-disease' also means that the treatment should always include both partners, the one with the illness as well as the other as both partners suffer but also have resources and can contribute to the coping process. Inclusion of the patient and his/her partner should not only happen at the beginning and end of a treatment but regularly during the intervention. By this means not only the remission of the illness is at stake but also the recovery of the whole system and the quality of the close relationship.

Illness Behavior and Care-Seeking

Howard Leventhal, Jessica Yu, and Elaine A Leventhal, Rutgers University, New Brunswick, NJ, USA

Abstract

Illness behavior, the belief that one is threatened by illness and in need of protective action, is typically initiated by changes in somatic experience and physical function that are interpreted as symptoms of an underlying threat to health. This interpretation involves matching of symptoms to schemas of illness. Schemas are products of personal experience, observations of and communication with others, and media exposure. The conviction and emotional worry that one is sick and the overuse of medical care in the absence of objective signs of disease may be sustained by the interplay between somatic sensation and emotional activation. We propose that a common mechanism underlies illness behavior for acute and chronic conditions and for somatoform disorders, and that the biological processes underlying the condition and the social processes surrounding the patient differentiate the observed differences in illness behaviors.

What Is Illness Behavior?

The phrase 'illness behavior' differentiates disease, a biological phenomenon (e.g., cancer, congestive heart failure, diabetes, etc.), from the behaviors associated with disease (Mechanic and Volkart, 1961; Parsons, 1975). These 'behaviors' range from the private experiences of symptoms, the meaning of the disease, and the emotions accompanying it, to the visible responses of 'sickness' such as fatigue, and the behaviors for cure and control such as the use of home remedies, medical care, being excused from work and household duties, and other behaviors involved in the sick role (Charmaz, 1999). Some investigators have differentiated illness behaviors, instigated and sustained by the presence of physical symptoms, from 'health behaviors,' actions taken due to concerns about the possibility of symptoms or under social pressures, and in the absence of physical symptoms (Kasl and Cobb, 1996). This distinction is questionable when we recognize that action can be taken to control the consequences of serious, diagnosed conditions that are asymptomatic, for example, using medication to control hypertension to avoid stroke or to control blood glucose to avoid diabetes. The distinction does, however, point to an extremely important aspect of human cognition: illnesses are represented at both an abstract, conceptual level, and an experiential or perceptual behavioral level (Leventhal et al., 2011); a distinction can be applied to mental representations of virtually all objects and events (Andrews et al., 2009). 'Illness behavior' seems best defined, therefore, as any action taken to cope with and manage anticipated threats of disease as well as the experience of diagnosed disease with and/or without symptoms. 'Sickness behavior,' a third phrase, refers to a syndrome of less visible somatic (e.g., fever) and overt symptoms (e.g., fatigue) generated by the immune systems response to pathogens (Dantzer, 2006); though not the focus of our presentation, the distinction may be critical for understanding illness behavior in the face of unexplained symptoms. Behaviors that affect health, positively or negatively, but not seen to be health relevant, would not be regarded as illness or health behaviors.

Why Is Illness Behavior Important?

Illness behaviors are important because of their impact on the daily functioning and quality of life of individuals, families, communities, and health care resources. The monetary impact and effects on quality outcomes have been a major focus of public discussion and political controversy and suggestions for resolving these problems vary widely both across and within Western and non-Western nations (Emanuel et al., 2012). Overuse of care in the absence of diagnosable disease is often cited as a cause of the high cost of medical care, including conditions labeled as somatoform disorders, somatic symptom disorder, chemical sensitivity, chronic fatigue syndrome, and most recently, Gulf War syndrome. In each case, patients attribute symptoms to an underlying disease that is currently not attributable to an identified, organic factor and symptoms and resulting use of care are attributed to the interplay of severe life stresses and personal vulnerabilities (Brown, 2004; Young, 2004). The 'worried well,' a phrase often applied to elderly women who are frequent participants in blood pressure screening programs, form another class of resource user, whose worrying drives behavior in the absence of disease and symptoms. The magnitude of the costs generated by these behaviors has been exaggerated, however, as they mainly involve the use of primary care services, and the entire primary sector consumes little more than 20% of the total health care budget.

In contrast to behaviors directly favoring overuse, illness behaviors that delay use of diagnostic and treatment regimens can add to the cost of health care when they result in medical crises and hospitalization. Failures in effective management are common for virtually all chronic conditions including asthma, coronary diseases, diabetes, depression, and cancers. These conditions along with ineffective and aggressive treatment in the last months of life are the major drivers of the high costs of health care. Chronic conditions challenge our everyday beliefs and perceptions of what it means to be sick; they are often asymptomatic, permanent, and require constant treatment and lifestyle changes. Dysfunctional illness behaviors can lead to failure to initiate and sustain rehabilitative regimens post-hospitalization, documented by data for myocardial infarction, strokes, and cancer (Phillips et al., 2001; WHO, 2003).

Nonparticipation may be due to individual and socially supported but mistaken beliefs such as "complete rest is essential to avoid death from heart attacks," or to misinterpretation of the pain from the healing of the surgical wounds as pain from failure to repair the underlying disease, such as the pain attributed to the effect of physical activity on a damaged heart.

Determinants of Illness Behavior and Care-Seeking

Given the number of syndromes used to describe illness behavior such as somatization, hypochondriasis, and body dysmorphic disorder, and the potential overlap with ineffective management for both chronic conditions and everyday illnesses, we will focus on the mechanisms common to all of these conditions that may promote or undermine effective self-management.

Symptoms and Care-Seeking

Everyday common sense tells us that symptoms, changes in somatic sensations and function, are stimuli for seeking care. As survey respondents report experiencing one new symptom each week of the year (Demers et al., 1980) and few individuals seek care 52 times in a year, it is clear that important as symptoms may be for care-seeking care, they are not sufficient prods for doing so. Cameron et al. (1993) interviewed clinic patients immediately prior to seeing their doctor and interviewed a matched control (age; family size; gender) very soon thereafter and reported that new symptoms were reported by 100% of the clinic patients and by 30% of the matched controls; symptoms mattered. In addition, the symptom reports of the clinic visitors differed from those of the matched controls; visitors in the latter group were less likely to have labeled or talked to someone about the symptoms and reported it was less disruptive of daily life. Symptoms prod care-seeking when they are perceived, elaborated upon, and represented as indicators of an underlying illness. The representation may range from that of a minor, self-limited and self-treatable problem to a potentially serious problem needing further evaluation, or a clear sign of a potentially painful and/or life-threatening illness that demands immediate attention from a qualified practitioner (Chrisman and Kleinman, 1983; Leventhal et al., 1980). Care-seeking typically follows an interpretation of somatic and functional deviations from the usual self-suggesting that one is 'ill,' unable to manage the condition on one's own, and therefore, in need of medical attention.

Symptom Interpretation: A Social–Psychological Process

The underlying proposition of our model of the cognitive and emotional processes that elaborate the meaning of illnesses, the common-sense model (CSM), asserts that somatic sensations and functional changes felt as deviations from ones 'normal' self are compared and matched to schemata of underlying conditions. If not in all instances, and certainly in the vast majority, the deviations are detected automatically, i.e., they are not the result of a conscious, 'executive driven' search. The generation of the initial, often provisional hypotheses regarding 'what is wrong' is partly if not completely automatic (Leventhal, et al., 2011). In many though not all instances, the detected deviation and the match becomes a conscious event that integrates the concrete experience and its schemata into a mental model or illness representation. The core, empirically supported proposition underlying CSM, is that illness representations are combinations of experience and abstract concepts, words and labels; for example, a painful lump integrated with a schema and labeled as a cancer, a painful joint integrated with a schema and labeled as arthritis, or an infectious sore integrated with a schema of concept of contact with dirt. That the linkage is likely automatic is supported by data showing that telling study participants that their blood pressure is elevated, false feedback for which they are subsequently debriefed, led to immediate reports of the same symptoms reported by patients with hypertension (Baumann et al., 1989), a sign of tight connectedness or symmetry between labels and symptoms, though symptoms are unrelated to objective readings of blood pressure. Representations have features or attributes in five areas, though they may not be complete at a given instant: (1) *Identity*, the location and pattern of the 'symptoms' combined with a label (initially self-diagnosed); (2) *Cause*, the experienced symptom or function is attributed to an external factor, observed (sharp object; dirt) or nonobserved external (virus, stress, luck), or an internal factor (genes); (3) *Time Lines*, rates of onset, duration, and time to resolve, each of which may be anchored in objective (clock) or perceived time; (4) *Consequences*, ranging from missed work and social contacts, costly treatments and unwelcome hospitalizations, etc. each of which can involve amalgams of concrete experience with concepts; (5) *Controllability*, both objective and subjective evidence of control by treatment. Thus, the variables in each area consist of abstraction, i.e., words and symbols, and concrete experience.

Contextual factors have a major impact on the elaboration of illness representations. Chrisman and Kleinman (1983) posit three such sets: (1) the popular sector, which comprises the individual's immediate social contacts, family, and community, who interpret the person's somatic changes in light of a shared belief system; (2) the folk sector, consisting of nonprofessional specialists, ethnic healers, religious or faith healers; and (3) the professional sector, or culturally defined specialists such as physicians, osteopaths, chiropractors, etc., the latter most salient in Western countries such as Europe and the USA. Initial hypotheses elaborating the representation of a possible illness usually come from the individual experiencing the change, then shared with, and elaborated by individuals in the popular sector (Cameron et al., 1993). The folk and professional sectors typically come into play when the shared, popular evaluation suggests a need for expert help. Interactions of an individual with people in each of the three sectors both provide possible interpretations of symptoms and most importantly, they reinforce the process by which deviations from 'normal self' are evaluated. In typical medical visits, the physician's review of the patients complaint may begin with "What bothers you?" followed by "Where is it?" "How long has it been going on?" "What did you do?" and "What happened when you did that?" The questions are consistent with the process involved in the patient's self-appraisal, a process that may have been conducted automatically, with little conscious awareness, but is validated as appropriate for

conscious and deliberate action. In summary, the initial self-evaluation process seeks to match deviations, i.e., symptoms and function, from the 'normal' self with illness schemata, generating hypotheses and/or representations of illnesses. These initial appraisals are typically discussed with family or friends (public sector) and followed on occasion by visits to a practitioner, either from the folk or professional sector. Each of these exchanges involves the interplay of intraindividual and interpersonal exchanges that are the focus of the "Common-Sense Model of Self Regulation," or CSM (Leventhal, et al., 2011).

The recommendations for management emerging from these intra- and interpersonal exchanges lead to 'action plans,' sometimes simple, at other times complex multistep plans for initiating treatment, ranging from do nothing (tincture of time), to short-term interventions, such as antibiotics or simple prostheses (splints) to promote healing, to alterations of lifestyle (diet and physical activity) and medical treatment that may last a lifetime. Each behavioral step initiates yet another set of implicit or explicit feedback loops for evaluating treatment efficacy. The evaluative process continues the intraindividual and interpersonal processes opened in the initial appraisal (popular; folk; professional).

Factors Affecting When the Interpretive Process Leads to Care-Seeking

Although care-seeking is highly likely in response to painful, disabling symptoms perceived as beyond individual control, they are not the factors most frequently leading to care-seeking. Many if not the majority of care-seeking episodes are initiated by specific factors in one or more of the five domains of the representation. For example, a symptom or functional change may elicit worry and concern and lead to seeking advice and care, if it exceeds the expected *time line* for minor and ignorable events and/or fails to match the schemata for a familiar, manageable illness. Rapid rate of onset, location (chest or arm; head) and pattern (sharp pain, dizziness, difficulty moving or speaking) can match the respective schemata for heart attack and stroke. Schemata for gastrointestinal ulcers, breast cancer, migraines, and head colds are defined by patterns in these domains; though the schemata will vary by culture and by individual, each disorder will have a set of features defining its *identity, time lines, control* (*response to treatment by self, consequences, and cause*) (Bishop, 1991). Symptoms that last longer than expected, are unfamiliar or match a schema for a life-threatening illness are likely to activate worry or fear, and whether the affective response leads to care-seeking or avoidance and delay, depends upon their perceived source and its properties. Care-seeking is likely when a disease is feared because its consequences are perceived as life-threatening or a lifelong reduction in function. The possibility of delay in care-seeking increases when a disease is perceived to be uncontrollable and when the perceived benefits of treatment do not outweigh its concerns (Horne et al., 1999). Consistent with 'commonsense' concerns likely increase for treatments with aversive side effects experienced with HIV treatment (Horne et al., 2004); inconsistent with common sense is the data showing that aversive side effects are associated with treatment benefit (Cameron et al., 2002).

Investigators have examined contextual modifiers of care-seeking that are not directly related to illness representations; life stress is a frequently studied example. It has been proposed and data have supported the hypothesis that life stresses are associated with increased probability of care-seeking (Mechanic, 1979). Moderators such as stress seldom work alone, however, and assuming they have consistent, indirect effects on care-seeking ignores the array of factors affecting the care-seeking process. Gortmaker et al. (1982) found that mothers were less likely to seek medical care for an ill child on the day of a stressful life event. A day later, however, when the event resolved and its barrier to care-seeking was removed, care-seeking frequency increased above that recorded in the absence of such events. How the relationship between life stressors and symptoms are interpreted adds further complexities to the process of care-seeking. Ambiguous symptoms such as fatigue and muscle aches are likely to be interpreted as signs of stress and not merit seeking care if they appear in the context of life stressors that have lasted for a few days. When similar symptoms appear in the context of life stressors that have lasted four or more weeks, the likelihood of care-seeking increases as symptoms in that context are likely to be interpreted as signs of stress-induced illness (Cameron et al., 1995). In this latter case, the rates of care-seeking are approximately the same as that recorded for symptoms that are distinct, nonstress signs of illness. It is worth noting that the duration for a stressor to influence the shift from not seeking to seeking care for ambiguous symptoms is roughly the same duration of exposure to life stresses that Cohen and colleagues (Cohen et al., 1998) reported for stress to increase susceptibility to cold viruses.

Social comparisons provide another set of contextual influences on the processes involved in self-diagnosis and care-seeking. For example, people are less likely to perceive symptoms as serious and in need of medical attention if other individuals (the popular sector) report similar symptoms (Croyle and Jemmott, 1991). The effect is likely when the underlying cause is seen as relatively benign, such as gastrointestinal distress by multiple members of one's party following an outing. This assumes that the distress is time limited and the trajectory for change is improving. Social comparisons also can moderate emotional response during treatment; patients awaiting major surgery are less distressed when waiting in a ward with revering, postsurgical patients in comparison to others awaiting treatment (Kulik and Mahler, 1997). Togetherness with patients in a common state of anxious anticipation, waiting for surgery, appears to be an occasion for emotional contagion; it does not have a calming effect, as some social–psychological models would predict. Waiting for surgery is less threatening when surrounded with postsurgical patients who are talking, alive, and seemingly doing well. The complexity of effects of social context on care-seeking is evident from findings of substantial increases in care-seeking and treatment following observation of symptoms and treatment in others. For example, survey respondents who observed symptoms in family and friends during a threatening flu epidemic were more likely to have been inoculated (Rosenstock et al., 1960). The seemingly contradictory relationships reflect interactions between the social context, the level of disease-associated threat, and the perceived efficacy (benefit

exceeding concerns) of treatment. The cognitive and affective processes underlying people's commonsense perceptions of the identity, cause, controllability, and consequences of disease make good sense psychologically though they may be consistent or inconsistent with biomedical interpretations.

Automatic and Deliberative Processes in Abnormal Illness Behavior

'Somatoform disorders' and 'abnormal illness behaviors' are terms encompassing an array of syndromes defined by the reporting of symptoms and the conviction that one is ill in the absence of medically definable disease. Brown's (2004) detailed analysis of the cognitive processes underlying many of these disorders proposes that symptom experiences are a product of a primary perceptual process, and are experienced as real, objective events. The analysis is consistent with the automatic matching of inputs to schemata in CSM, the basic perceptual process for perceiving deviations from the 'normal' self; they too are perceived as real. The outcome of the match may or may not be biomedically valid. Both Brown and the CSM differentiate these automatic perceptions from the deliberative, secondary, executive systems that attend to and attempt to make sense of and act to regulate symptom experience. Somatoform disorders therefore, involve the following two steps: (1) Patients' perceptual experiences are experienced as real and interpreted and continually updated by the cognitive and affective mechanisms underlying the patient's commonsense framework. And the resulting mental models created by these processes may differ from the interpretations based on the conceptual framework of biomedicine the latter is abetted by a variety of 'objective' measures. (2) The patients' mental models and behaviors are labeled as a somatoform disorder because the behavioral state, the symptoms, emotions, and actions, persist in the absence of identifiable pathology and are seemingly impervious to medical explanation.

A number of factors have been proposed to account for the persistence of symptom experience and physical and cognitive dysfunction in the absence of supportive, biomedical evidence. These factors are believed to focus attention on and magnify the salience of benign somatic sensations thereby converting them into symptoms of illness; the result being repeated care-seeking and doctor shopping (Kellner, 1990; Kirmayer and Robbins, 1991; Brown, 2004). *Trait negative affect* (NA) (a relatively stable feature of personality characterized by self-reports that one's mood or emotional state is usually worried, anxious, or depressed), is a frequently mentioned candidate as individuals scoring high on measures of this trait report a larger number of somatic complaints than do low-scoring individuals. There is little evidence, however, that persons high on trait NA make greater use of health care (Watson and Pennebaker, 1989), and it is likely that the vast majority of individuals high on trait NA are well aware of the difference between specific symptoms of illness and somatic signs of emotional distress; that they do so is validated in several studies (e.g., Mora et al., 2002; Rabin et al., 2001). It is also clear that the percentage of the population with somatoform disorders, fewer perhaps than 4%, is far less than the percentage of individuals with high scores on trait NA (Robins et al., 1984). Thus, while individuals in both categories may report worry about health, worry is not equivalent to or sufficient for interpreting and attributing sensations to illness.

There is reason to believe, however, that personal factors such as trait NA and social factors such as expression of concerns about own and others health by family members and friends, provide a context for the formation of somatoform disorders. These factors may come into play by first focusing attention on somatic sensations and by then activating emotion and worry and linking the two by shifting attention to the activated emotional state (Nakao and Barsky, 2007). It may take but little encouragement to convert the emotional state into sustained worry, the encouragement arising either from within the individual's own history, as is often the case post-treatment for breast cancer, or of observation of illness in another, e.g., observation of cancer and/or cardiac death in a family member or close friend (Nakao and Barsky, 2007).

Thus, momentary states of worry or fear can readily become repetitive and chronic, if activated by the ongoing monitoring of the self-system that can automatically detect somatic and functional deviations from the normal self. The repeated scanning and activation, therefore, can convert momentary concerns into repetitive, chronic conditions; literally a self-sustaining state of ruminative worry. The linkage of emotional activity with somatic sensations may be facilitated by the overlap between their respective properties, e.g., symptoms such as fatigue and restlessness are shared by emotional upset and sickness behaviors. In addition to the major role played by emotional activation or worrying in eliciting and maintaining the search for causes and cures characteristic of illness behavior, emotional activation can also increase muscle tension and amplifying somatic sensations eliciting the affective process. Different moderators may further differentiate these response patterns leading to multiple diagnostic categories (Brown, 2004). While the hypothesized mechanism remains to be tested, it is worth noting that it appears in many ways the inverse of the procedures to deactivate emotional responses during medical procedure, e.g., expecting, normalizing, and being response ready while attending to concrete sensory experiences during noxious medical examination (Johnson, 1975) or during childbirth (Leventhal, 1986), and desensitization therapies (Lang et al., 1983).

Chronic Illness, the Self, and Illness Behavior

If, as we propose, the same cognitive and affective mechanisms underlie illness behaviors associated with acute and chronic conditions and somatoform disorders, it is essential to recognize that each specific acute or chronic disease creates a unique physiological, mechanical, and anatomical context. Different demands are made on the behavioral system with variation in the input from the disease process, from its pattern and location of existent sensations (identity), time lines, causes, means of control, and consequences. Three other factors come into play for chronic diseases. First, they are diseases that last and one must live with for a lifetime. Second, chronic conditions require adjusting not only to the illness itself, but to the interaction of the illness with the cognitive and physical changes of aging. Third, most elderly live with multiple chronic conditions. These conditions impact physical function, restrict

participation in daily activities, can have severe impacts on memory and thought, the various dementias, and these constraints are often associated with increases in NA and declines in positive (Zeiss et al., 1996). Managing many, largely intractable, diseases can contribute to a sense of hopelessness, an integral component of depression, and lower quality of life (Vileikyte et al., 2005). The evidence indicates, therefore, that functional decline associated with both advanced age and chronic illness carries additional, psychological hazards, and these psychological changes reinforce the very functional deficits that initiated them.

Illness Behavior and the Management of Chronic Disease

Many of the chronic conditions prevalent in the later years of life are largely asymptomatic; elevations in blood glucose and blood pressure in hypertension are asymptomatic until visible in systemic damage. The genetic changes and proliferation of cancers and formation of arterial plaques can progress in complete silence until a tumor is detected and/or the individual faces a myocardial infarct or stroke. And the asthmatic patient, who experiences episodes of sometimes violent and potentially life-threatening attacks, may be largely unaware of the silent inflammatory process that underlies the disease. All of these conditions require action based upon action plans independent of and at times inconsistent with the concrete experiences associated with everyday, acute conditions that have stimulated illness behavior for most of life.

Unlike somatoform disorders, where somatic cues conditioned to affective worry both amplify somatic sensations and produce persistent illness behavior, conceptual processes need to be the major drivers of illness behaviors for chronic illnesses. Individual, focus group, and qualitative data suggest how the transition might occur. For example, after narrating how she manages her asthma, an interviewee was asked, "Do you think you can always tell you have asthma?"; somewhat taken aback she replied, "I guess from what I've told you I must think it is always symptomatic." Focus groups of patients with congestive heart failure, whose left ventricles eject 40% or less of the blood at a contraction, may fail to perceive problems breathing lying in bed and chronic tiredness and swollen legs as symptoms of coronary disease. As they explain, feeling "kind of tired … just didn't seem to be anything out of the ordinary" and fail to see symptoms distributed at different times as in need of care or part of their heart conditions: "… Oh, I guess that I could have gone to the doctor after I had that collapse on the hallway floor." Their symptoms do not match the schema for cardiovascular disease: "When you hear about having heart problems, … you're supposed to feel maybe a pain in your left arm, maybe a pain in your chest, or pressure … it would have been more clear to me if I had chest pain then I would have said, okay, I'll call and say I'm having chest pain …" (Horowitz et al., 2004). Data from over 400 patients interviewed soon after they were hospitalized for a myocardial infarction support the qualitative reports (Bunde and Martin, 2006). Delay in care-seeking was brief among patients experiencing chest and arm pain and patients who had a prior history of cardiovascular disease. Delay was lengthier among those reporting fatigue, sleep disturbance, and symptoms perceived as gastrointestinal. Location, pattern, rate of onset, etc., matched a coronary event for quick care seekers and aging or an alternative benign condition for those who took longer, endangering their lives and recovery.

A variety of cognitively based beliefs about the self and treatments have been identified for their impact on illness behaviors. The belief that it is important to 'conserve resources' as one ages (Leventhal and Crouch, 1997) encourages levels of inactivity that can be maladaptive for living with many chronic illnesses. For example, it is associated with increases in pain over a 3-year time span in rheumatoid arthritis patients (van Lankveld et al., 2000), and among coronary patients, it encourages avoidance of the physical activity needed for improved cardiac function. A contrasting cognitive factor, the belief that a strategy of vigorous engagement is necessary for good health, can lead cardiac and cancer patients to adopt behaviors such as jogging and the use of herbal supplements in order to strengthen the disease-fighting capacity of their immune system. Although exercise is effective in reducing risk of mortality (Bijnen et al., 1999) few herbals deliver on their promises for health gains and some generate risk as they may interact adversely with chemotherapies of proven value, and many patients using supplements fail to communicate their use to their physicians. People's beliefs about their bodies' tolerance for medication (e.g., "Even small amounts of medicines can upset my body") are associated with negative views of medicine and lower levels of adherence. This has been found in patients treated for HIV and hypertension, a sample of undergraduates and international travelers who held these beliefs reported more symptoms following vaccination.

Illness Behavior: The Self and Social Context

Each and many other examples not here cited illustrate the operation of the cognitive, affective, and behavioral mechanisms involved in managing acute and chronic conditions and somatoform disorders. Illness behaviors that are adaptive and maladaptive as seen from the perspective of biomedicine can be seen as the product of a system in which behavior is controlled by concrete perceptual experience at one or more points in time, and by abstract conceptual factors at others. The alternation of control reflects the complexity and hierarchical structure of the mental models that are generated by the match of symptoms, diagnoses, and observation of illness in others to illness schemata; these processes are central to human cognition (Andrews et al., 2009).

Although the focus of our presentation on the mechanism critical for the immediate perception and conscious evaluation of symptoms for acute, chronic, and somatoform disorders is biased toward the 'intrapsychic,' it is important to reiterate that the cognitive, affective, and behavioral facets are embedded in individual history and social context. The sense of self, physical, cognitive, and social, represents the integration of the interaction of life experience with biological processes and affect both how self-perception and the formation of schemata for acute, chronic, and somatoform disorders. Illness and illness behavior will feedback to and influence the self-system: how individuals define themselves, and how they act in relation to others, and to the tasks of daily life. The functional and emotional impact of chronic illness and its permanence presents a challenge to the very definition of the self. Thus, chronic

illness represents a challenge both from the bottom-up – its symptoms, signs, dysfunctions, and effects – and from the top-down – the meaning of these signs and symptoms (Leventhal et al., 1999). Prior self-identities and competencies and the social context (the popular (family), folk, and professional sectors) both directly influence and moderate these changes in self. Intellectual, emotional, and social resources can support illness behaviors, which are effective for the management of disease even when disease is not curable and can have negative effects of health outcomes by undermining individual autonomy. Critical and hostile interpersonal exchanges within couples can impact the expression of symptoms and maladaptive illness behaviors (Burns et al., 2013). Illness behaviors effective for disease management can strengthen the individual's sense of competence, create new and strengthen existent identities, and enhance the individual's ability to participate in life despite the drastic impact of illness on the physical self. Illness behavior at its best, i.e., the performance of new actions in managing the self with disease, can be the source of new, stable identities that define the value of life.

Abstract

Neuroimaging of structural and functional alterations in mental disorders is a rapidly growing field of research with strong relevance for neurobiological theories of mental disorders. Findings concerning the neural correlates of psychopathological symptoms and associated alterations in cognitive and emotional processing, however, strongly depend on specific neuroimaging methods, experimental designs, and analytical procedures. The present article highlights past achievements in the field, the suitability and limitations of imaging methods and experimental designs, and their informational value for clinical psychology and future research.

Introduction

The use of neuroimaging methods in the field of biological psychiatry and clinical psychology has exponentially increased during the past 20 years, thereby promoting scientific theories and models about neurobiological factors contributing to psychopathology. The first studies investigating the relationship between psychopathological symptoms and brain metabolism emerged in the early 1980s by the use of single-photon emission computed tomography (SPECT) and positron emission tomography (PET; Buchsbaum et al., 1982). A new area of brain imaging started with the development and increased usage of functional magnetic resonance imaging (fMRI) in the mid-1990s (Wenz et al., 1994). Today, we have access to a multitude of structural and functional imaging studies highlighting the neural correlates of all kinds of mental disorders and clinical symptoms. Several of those studies had significant influence on our understanding of psychopathology and disorder-related neural processing. For instance, a crucial early fMRI study of Dierks et al. (1999) showed that auditory hallucinations in schizophrenic patients activated the same auditory brain regions as recorded speech does. Due to this study, the sensory quality of hallucinations became sort of 'visible' in terms of neurobiological parameters. Additionally, it highlighted the difficulty to differentiate between real speech and imagined speech psychotic patients typically experience. This was one of the first studies that demonstrated not only how functional imaging can contribute to the neurophysiological understanding but how it can also provide evidence to support specific psychological theories of mental illness symptoms.

The present article gives an overview of (1) the relevant imaging methods, (2) the general aims and scope of neuroimaging research of mental disorders, (3) experimental designs and analytical strategies, and (4) future challenges.

Imaging Techniques in Clinical Psychology

The technical progress in the field of brain imaging methods is immense (for a detailed review, see Bandettini, 2009), providing more and more sophisticated techniques to disentangle the neural correlates of mental disorders. In a narrower sense, all methods that enable the regional or systemic structural or functional localization of dysfunctional processing are considered as brain imaging techniques. These are primarily methods with moderate to high spatial resolution, which are based on local brain tissue, neurovascular, and metabolic measures, such as (f)MRI, functional near-infrared spectroscopy (fNIRS), PET, and SPECT. Computed tomography also belongs to this category, although rather rarely used. In a broader perspective and even though not further discussed in the present article, electrophysiological methods such as electroencephalography (EEG) and magnetoencephalography (MEG) are also considered as imaging methods despite lower spatial resolution. Instead, they offer detailed insight into the temporal dynamics of processing. A comparison of these methods with regard to spatial and temporal resolution and possible research fields is presented in **Table 1**.

Apart from their varying spatial and temporal resolution, functional imaging methods can be subdivided according to the measures they rely on and the processes they refer to. Direct recording of neural functioning is possible with electrophysiological methods, i.e., EEG and MEG. Hemodynamic measures such as fMRI and fNIRS rely on the principle of neurovascular coupling, assessing changes in regional hemoglobin concentrations. Therefore, they are indirect measures of brain function because they refer to processes that are closely related to neural functioning, i.e., oxygen consumption and regional cerebral blood flow. PET and SPECT reflect the biochemical processes that take place during neural activation and also rely on the principle of measuring regional cerebral blood flow changes. However, with these techniques it is possible through the use of different radioactive tracers to have a closer look at metabolic processes other than oxygen consumption (i.e., glucose metabolism or neurotransmitter-related alterations). As a consequence, molecular investigations of neural functioning in humans are only possible using PET and SPECT and despite the use of radiation, on cellular level, neurotransmitter functioning can only be assessed by these methods.

The use of imaging techniques, however, usually requires a great deal of time and effort. Especially with increasing spatial resolution, methods become more expensive and measurements are time consuming because of increasing preparation

Table 1 Overview of neuroimaging and electrophysiological methods used in clinical psychology

Technique	*Spatial resolution*	*Temporal resolution*	*Potential research areas*
MRI	Relatively high	N/A	Morphology Volume
CT	Moderate/ High	N/A	Morphology Volume
SPECT	Moderate	Very low	Functional metabolism Regional metabolism Connectivity
PET	Moderate	Very low	Functional metabolism Regional metabolism Connectivity
fMRI	High	Moderate	Functional hemodynamics Regional hemodynamics Connectivity
fNIRS	Fair	Moderate	Functional hemodynamics Regional hemodynamics Connectivity
MEG	Low	Very high	Temporal processing Lateralization
EEG	Poor	Very high	Temporal processing Lateralization

This is a slightly modified version of the table presented in our article 'Imaging Methods in Psychotherapy' (see Imaging methods in psychotherapy).
CT: computed tomography; EEG: electroencephalography; (f)MRI: (functional) magnetic resonance imaging; fNIRS: functional near-infrared spectroscopy; MEG: magnetoencephalography; PET: positron emission tomography; SPECT: single-photon emission computed tomography.

time. Less expensive techniques such as EEG and fNIRS are advantageous in their ecological validity. They can be applied in a quiet and more natural measurement setting and have no side effects. In contrast, bigger apparatuses are accompanied by loud noise, a narrow and uncomfortable measurement setting, or undesirable side effects due to radioactive tracers or X-rays. With increasing psychopathology or anxiousness, their application in clinical populations becomes difficult. Particularly anxious and claustrophobic individuals are less compliant with such measurements. Symptoms of a disorder itself, such as paranoid thinking in schizophrenia, can also be problematic in brain imaging studies. As a consequence and because all of these methods are more or less susceptible to motion artifacts, the signal-to-noise ratio can decrease significantly in clinical studies. Further problems for the interpretation of hemodynamic functional imaging studies are, for example, changes in baseline activation due to state-induced alterations in overall blood flow and oxygen concentration (e.g., hypocapnia due to hyperventilation in anxious individuals; Giardino et al., 2007).

The systems-level approach of primarily fMRI, fNIRS, EEG, and MEG offers a multitude of detailed research questions and allows for the study of neural clusters, modules, projections, structures, connectivity, functional specificity, and temporal aspects of processing. Very sophisticated acquisition and analyzing techniques exist (e.g., pattern classification; Haxby, 2012) and are constantly developed to enable even more elegant and noninvasive imaging of the human brain (Bandettini, 2009). Advanced structural imaging techniques such as diffusion tensor imaging allow for a more detailed study of the neural pathways and their alterations in mental illness. However, all mentioned functional imaging methods only provide information about correlational brain–behavior relationships. Causal inferences can only be drawn from brain stimulation studies using transcranial magnetic stimulation (TMS) or transcranial direct-current stimulation (tDCS) in varying spatial resolution.

Aims and Scope of Neuroimaging Research of Mental Disorders

Neuroimaging research in the field of mental disorders is an interdisciplinary research area, which brings together psychiatrists, clinical psychologists, and neuroscientists from other professions. The objectives of this research are manifold. Even though not mutually exclusive, they can broadly be divided into (1) those that aim to improve the basic knowledge about the structural and functional neural alterations that accompany mental illness and (2) those that aim to improve the prevention, diagnostics, treatment, and prediction of relapses of clinical symptoms. The potential research questions and resulting conclusions of such research, however, always depend on the neuroimaging methods and the experimental and analytical procedures they rely on.

Regarding the first aim, it is clear that the understanding of mental illness includes a detailed investigation of patients displaying a certain psychopathological behavior. However, it is primarily the study of psychological processes that manifest themselves in a dysfunctional way in patients, which is of high relevance for the field of clinical psychology. Nowadays, disorder-related characteristics are rather seen on a continuum with regard to their frequency and intensity instead of a binary differentiation between either being disordered or not. As such, characteristics that are associated with certain disorders are also present to some degree in healthy subjects either in the form of a current state or a personality trait. For instance, anxiety sensitivity, a trait that predominantly indicates how anxious an individual reacts to habitually occurring bodily sensations, seems to be normally distributed over the average population but is significantly increased in patients with panic disorder (McNally, 2002). In healthy subjects, heightened anxiety sensitivity is related to the experience of single spontaneous panic attacks and is supposed to constitute a risk factor for panic disorder (McNally, 2002). For clinical neuroscience research, the comparison of healthy individuals displaying low and high anxiety sensitivity may help to disentangle the neural correlates of increased fear of bodily reactions, a trait that represents a key symptom in panic disorder. Taken together, although the investigation of patients is of crucial relevance, the study of healthy individuals marks a substantial part for the field of clinical neuroscience.

Further, to increase the knowledge about neurobiological underpinnings of mental illness, it is important to gain insight into the associated mechanisms of dysfunctional processing and to distinguish them from otherwise normal processing. For example, for the successful localization of auditory hallucinations in the schizophrenic brain, it is also interesting to find out whether patients show general alterations in auditory processing and in how far the hallucinatory neural patterns differ from those of listening to externally (Dierks et al., 1999) or internally

generated speech (Simons et al., 2010). In general, psychiatric disorders are accompanied by alterations in many domains of processing such as perception, attention, cognition, language, memory, emotion, and motor function. This entails a vast variety of open research questions and experimental designs.

With respect to the second aim, the relevance of imaging studies for the clinical practice, many studies are dedicated to find the predictors of developing a certain disorder or factors forecasting relapse. A long-term goal of clinical imaging research is the prediction of the treatment response. Recent studies tried to identify neural patterns that can predict clinical outcome (Siegle et al., 2006) or correlate with global improvement (Buchheim et al., 2012). The idea behind such prospective studies is a more individualized and effective treatment by getting a better estimate of the course of disease, thereby lowering costs and efforts for the health care system. However, neuroimaging is relatively expensive and time-consuming prospective studies are rare (Vannini et al., 2007; Chan et al., 2003). Instead, recent studies increasingly focused on neural processes that are associated with clinical outcome (e.g., Siegle et al., 2006) or investigated etiological factors such as certain risk genotypes and how they influence brain functioning (Domschke et al., 2011). Finding neurobiological markers may further support the diagnostic process and may help to exclude differential diagnoses (e.g., Hahn et al., 2010). The identification of such markers may in turn represent a potential target for treatments. Neurofeedback, for instance, has been successfully used as a treatment strategy in attention-deficit hyperactivity disorder (ADHD) using EEG (Fuchs et al., 2003). Ongoing developments in real-time imaging techniques using fMRI and fNIRS are also promising (Weiskopf, 2012; Mihara et al., 2012). In addition, the use of brain stimulation techniques such as TMS, tDCS, or deep brain stimulation received increasing attention as potential treatments for depression and anxiety during recent years (Mayberg et al., 2005; Zwanzger et al., 2009). Brain stimulation, however, relies on the localization of critical target regions within the brain that can only be identified by neuroimaging. Furthermore, brain imaging techniques are increasingly used to investigate the dynamics of medical and psychotherapeutic treatment and clinical improvement. For detailed information about the monitoring of therapy progress by means of imaging techniques, the reader is referred to our article 'Imaging Methods in Psychotherapy' (see Imaging Methods in Psychotherapy).

Neuroimaging of mental disorders covers the whole spectrum of disorders with an exponentially increasing number of published studies. This is illustrated in **Figure 1** by providing estimated numbers of present review articles on fMRI studies related to mental disorders (last updated in February 2014). While disorders such as schizophrenia and depression received most attention in the beginning of human brain imaging research, other conditions such as anxiety disorders (Dresler et al., 2013), eating disorders (van Kuyck et al., 2009), addiction (Goldstein and Volkow, 2011), and ADHD (Bush et al., 2005) have increasingly come into focus during the past decade. In contrast, personality disorders, with the exception of borderline disorder (Driessen et al., 2004), have been widely disregarded until now. Psychiatric neuroscience equally refers to the assessment of adult populations as well as children and adolescents (Bush et al., 2005) and the age of the population of interest naturally varies with the respective disorder (e.g., ADHD vs dementia). Moreover, brain imaging research in clinical psychology is not restricted to mental disorders but extends into other fields such as clinical neuropsychology (Reichenberg and Harvey, 2007) and medical psychology (e.g., Gianaros and Sheu, 2009), which, however, cannot be discussed here.

Neuroimaging research of mental disorders is related to both structural and functional alterations. While functional measures represent stimuli-related, task-related, or so-called resting-state-related (Broyd et al., 2009) brain activation (metabolism, hemodynamics, electrical activity; see above), structural measurements inform about alterations in gray or white matter. Both may be relevant for clinical psychology. Structural alterations may represent a general factor for psychopathology. For structural imaging, several studies have found regional or overall alterations in brain tissue. Most prominent here are the studies on patients suffering from posttraumatic stress disorder (PTSD). Several studies reported smaller hippocampal volume in these patients; however, it is discussed whether this finding represents a cause rather than a consequence of the disorder (Gilbertson et al., 2002). Similarly, overall brain atrophy is a characteristic of various conditions such as Alzheimer's disease and alcohol dependence (Chan et al., 2003; Bjork et al., 2003). However, this research seems to be less relevant for clinical psychologists than functional imaging. In contrast to structural imaging, functional imaging research refers to the mapping of single symptoms or characteristics in processing of the disorder or disorder-related state or trait rather than mapping the disorder as a whole. It is important to keep in mind that every psychopathological syndrome represents a collection of clinical symptoms that can vary with regard to their frequency, intensity, and compilation. Furthermore, neuroimaging findings are also strongly dependent on experimental settings, imaging methods, and analytical procedures. This poses limitations to the generalizability of results from clinical imaging studies and their interpretation as discussed in the following article.

Experimental and Analytical Procedures in Functional Imaging of Mental Disorders

The informative value of functional imaging studies depends to a large degree on the experimental setting. For example, for panic disorder, previous studies reported divergent findings regarding prefrontal functioning. Many studies found hypoactivation in patients compared to controls while others observed the contrary (for a review, see Dresler et al., 2013). Without a consideration of the experimental task and the assumed underlying processes, no conclusion can be drawn since symptom provocation studies are known to activate partly similar prefrontal areas that were found to be hypoactive in emotion regulation studies in patients (Etkin et al., 2011). Similarly, many disorders share certain symptoms or information processing biases. Selective attention or avoidance behavior, for instance, is characteristic of many disorders such as anxiety and trauma-related disorders, depression, or eating disorders. As such, findings from the investigation of such

Figure 1 Present number of review studies about psychopathological conditions investigated by using fMRI. The upper panel shows the number of currently available review articles about fMRI research studies on the main conditions that are encountered in clinical psychology and psychiatry. Results were obtained through a literature search on PubMed searching for titles or abstracts comprising the keywords 'review' and 'fMRI' in addition to the disorder name as depicted above (latest update on 25 February 2014). The lower panel presents how fMRI review studies are divided into certain clinical disorders.

particular processes using adequate experimental paradigms such as the dot-probe task or approach-avoidance task might be transferable from one psychopathological condition to the other. In turn, the validity of the task must be scrutinized since it is essential that the symptom or the process that is intended to be mapped in the brain is actually targeted by the experimental manipulation. To conclude, there is no experimental task that covers all psychopathological alterations of a given disorder. Thus, it seems to be essential to investigate what kind of information processing is affected at the brain level and how the temporal features of these alterations look like, which, of course might differ in different brain regions (Schulz et al., 2013).

The variety of experimental designs that has been tested in clinical neuroimaging is immense. Now, there are hundreds of studies focusing on differential aspects of psychological processing, using a multitude of different stimuli and experimental settings. The currently available literature in the field covers all domains of general psychology, i.e., emotion, cognition, perception, sensation, motor function, memory, language, and learning. These domains, in turn, split up in even more specialized and detailed research fields, with an often very

specific focus on a particular disorder. Findings from basic research are instantaneously transferred to clinical studies and different patient groups. Various types of learning, for instance, have received a great deal of attention during past years (Maren et al., 2013). Here, and in contrast to higher order cognitive functions, findings and experimental designs can be almost directly transferred from animal studies to the human model. Due to such translational approaches, we got a thorough understanding about the basic neural processes accompanying different types of learning such as appetitive conditioning or fear learning (Moscarello and LeDoux, 2013; Vanelzakker et al., 2014). And still, research is ongoing, discovering even more finer details of those particular processes underlying human feeling and thinking.

The used experimental designs can be broadly subdivided in two categories: unspecific processes and symptom provocation/disorder-related tasks. Regarding the first point, a great deal of studies investigated general changes in neural functioning that accompany mental illness and are not primarily associated with the symptomatology of a given disorder. These unspecific processes, however, vary depending on the disorder. For example, studies on cognitive control are symptom-based in disorders such as schizophrenia but rather unrelated when it comes to anxiety disorders, whereas alterations in emotional processing are primarily linked to mood and anxiety disorders. Both cognitive functioning and emotional responsiveness have been studied extensively with regard to many mental disorders and, although not representing core symptoms, many of these studies found differences in neural functioning when compared to controls. Verbal fluency, for instance, a task requiring both linguistic and cognitive skills, has been associated with prefrontal hypofunction in a broad range of disorders (Dieler et al., 2012). This finding reflects the advantage of neuroimaging over neuropsychological tests because even in the absence of any behavioral performance deficits, neural alterations can be detected. Similarly, contextual learning plays an important role in many disorders and might lead to changes within the involved neural networks (Maren et al., 2013). To date, fear learning, context conditioning, and fear extinction have been primarily of interest in anxiety disorders because it is supposed that they reflect the neural processes that take place during the acquisition and recovery of clinical symptoms.

With the theoretical shift from the initial assumption that single neural modules underlie particular types of processing to the theory that such complex behavior is rather based on entire neural networks, also resting-state studies received increasing attention during recent years. Temporal correlations between spontaneous fluctuations in the measurement signal are supposed to reflect functional connectivity across different brain regions. Changes in this resting-state network have been predominantly reported for patients suffering from Alzheimer's disease and also for other clinical conditions (Broyd et al., 2009).

The other broad category of tasks focuses on particular symptom-related or disorder-relevant processes primarily during presentation of emotional stimuli. Symptom provocation designs (e.g., Boehme et al., 2013), information processing bias tasks (e.g., Luijten et al., 2011), the presentation of disorder-related stimuli without clear symptom provocation (e.g., during different task conditions; Straube et al., 2004), emotional learning (Maren et al., 2013), and emotion regulation tasks (e.g., Goldin et al., 2009b) belong to this category. The experimental tasks used for symptom provocation and disorder-related alterations may vary completely with the particular range of symptoms/assumed psychological alterations of a certain disorder. Also, the clinical picture may vary to a great extent depending on the disorder. While anxiety disorder patients often exhibit relatively homogenous patterns of clinical symptoms such as fear responses and avoidance behavior to aversive stimuli, mood disorders such as depression, or bipolar disorder are characterized by a more heterogeneous clinical picture. Consequently, symptom-based brain imaging in those disorders requires a finer selection of subsamples according to present symptoms (e.g., rumination, thought suppression). Other disorders, in contrast, completely differ with respect to their clinical manifestation but share certain symptoms. Impulsive behavior, for example, represents a common symptom in ADHD, addiction, or borderline personality disorder.

Thus, the provocation and testing of clinical symptoms in neuroimaging represents a great challenge. As variable as clinical symptoms are, the different are experimental designs and stimuli. Studies trying to catch spontaneously occurring symptoms such as hallucinations or panic attacks are rare (Dierks et al., 1999) and reports often represent rather incidental findings (Dresler et al., 2011). Instead of such passive designs, the majority of studies use stimuli for active and experimentally controlled symptom provocation. Particularly, anxiety disorders are suited for the investigation of disorder-related symptoms during brain imaging because anxiety symptoms can be provoked relatively easily by means of a range of different experimental manipulations. Typical stimuli that have been used include several kinds of pictorial or auditory stimuli (**Table 2**).

Chemosensory stimuli are less frequently used because of their rather minor relevance for symptom provocation in most disorders. However, a study of Vermetten et al. (2007) demonstrated the suitability of odors to provoke symptoms in PTSD. The authors exposed combat-related PTSD patients to the smell of diesel while undergoing PET and found an activation increase in fear-related brain regions (i.e., amygdala, insula, medial prefrontal cortex, and anterior cingulate cortex). Apart from sensory stimulus presentation, there are also pharmacological challenge studies, in which a pharmacological agent is administered to actively induce panic symptoms during the measurement. In those studies, an often used panicogenic agent is cholecystokinin-tetrapeptide (CCK-4), which leads to a profound increase in physiological arousal and anxiousness. CCK-4 reliably provokes panic attacks in the majority of both patients with panic disorder and healthy subjects and allows for a relatively precise timing of symptoms (Zwanzger et al., 2013; Dresler et al., 2013).

In contrast to pharmacological provocation, many studies work with experimental manipulations similar to psychotherapeutic exposition techniques. In panic disorder, for instance, *in vivo* exposition during brain imaging is achieved by interoception or hyperventilation (Dresler et al., 2013). For patients suffering from social anxiety disorder (SAD), public speaking or being observed by others represents a highly threatening situation, which has been successfully used to elicit symptoms during a PET (Tillfors et al., 2001) or fMRI measurement

Table 2 Stimuli being used for symptom provocation or emotional processing in anxiety disorders

	Pictorial	*Auditory*	*Chemosensory*	*Pharmacological*	*Other*
General	Pictures Videos Words	Sounds Imagery scripts	Odors Tastes	Psychotropic agents	Conditioned stimuli
PD	Biofeedback (e.g., heart rate, skin conductance, respiration, blood pressure)	Biofeedback (e.g., heart rate or respiration)		Panicogenic agents (e.g., CCK-4, caffeine)	Interoception Hyperventilation
SAD	Facial stimuli Performance feedback Video feedback of own behavior or reactions	Angry voices Performance feedback Listening to own voice			Being under observation (e.g., being filmed) Performance situations under observation (e.g., Trier social stress test)
PTSD	Trauma-related situations or trigger items	Trauma-related situations or trigger items Voices (e.g., yelling, angry voices, crying) Startle sounds	Trauma-related odors or tastes		

The table presents different stimulus classes that have been used in neuroimaging research to provoke clinical symptoms in anxiety disorders. Particular types of stimuli are listed for three frequently investigated clinical conditions: panic disorder (PD), social anxiety disorder (SAD), and posttraumatic stress disorder (PTSD).

(Boehme et al., 2013). The latter study provides clear evidence that activations in specific regions show different temporal profiles, with an initial response of the amygdala, but more sustained responses in other regions (**Figure 2**).

Apart from exposure to certain auditory or pictorial triggers, the recall of traumatic memories marks an effective *in sensu* strategy to provoke feelings of anxiousness and helplessness in PTSD patients undergoing fMRI (Driessen et al., 2004). Similarly, anxiousness or dissociative states can be elicited by script-driven imagery (Lanius et al., 2002). In contrast to pharmacological challenges, these kinds of manipulations are noninvasive. On the other hand, it is difficult to control for the extent of actual exposure since the effectiveness of the task depends on the cooperation of subjects and willingness to actively engage in the experimental task. Similar as during the pictorial presentation of aversive stimuli, subjects might disengage from the task and try to avoid exposure by looking away or even dissociating.

Figure 2 The figure displays findings from a fMRI study by Boehme et al. (2013) investigating the neural correlates during anticipation of a public-speaking task in a group of SAD patients compared to healthy controls. The results showed that during the first 20 s of the aversive anticipation period, patients displayed a profound increase in amygdala activation compared to the control task, whereas a decrease in amygdala activation was found for the same contrast in the control group. This activation increase was only present during the earlier phases of anticipation and diminished over the course of the entire anticipation period (40 s in total). Furthermore, anticipation of the speech task versus control condition led to an additional activation increase in the insula and a simultaneous decrease in the ventral striatum in patients compared to controls over the entire anticipatory period. The decrease in the latter region was negatively correlated with the reported anticipatory anxiety in the patient group. The figure has originally been published in Boehme, S., Ritter, V., Tefikow, S., Stangier, U., Strauss, B., Miltner, W.H.R., Straube, T., 2013. Brain activation during anticipatory anxiety in social anxiety disorder. Social Cognitive and Affective Neuroscience. http://dx.doi.org/10.1093/scan/nst129. Reproduced with kind permission from Oxford University Press.

While studies on anxiety disorders use primarily emotional stimuli for symptom provocation and changed information processing, other disorders are rather related to difficulties in other domains such as cognition, attention, or memory. Schizophrenic patients, for example, experience a range of deficits in executive functioning that can be triggered experimentally by cognitive tasks. The core symptoms of ADHD are attentional deficits, which can be easily assessed during functional imaging by means of conventional neuropsychological tests of attention such as the continuous performance task. The neurodegenerative processes of dementia are associated with a continuous aggravation of working memory performance particularly in early stages of the disease (i.e., mild cognitive impairment) during which experimental testing can be still accomplished by the patients.

Other tasks intend to investigate processes that are related to (dysfunctional) learning and emotion regulation. Several studies refer to strategies used also in cognitive-behavioral treatment such as exposure or cognitive restructuring. Direct exposure to disorder-related stimuli leads to the elicitation of clinical symptoms as described above, whereas repeated and prolonged exposure causes habituation, a process marking the core element of behavioral treatment. Therefore, and because extinction learning can be easily performed in other species allowing for a translational research approach, many imaging studies focused on (impaired) extinction learning in both healthy and clinical populations (e.g., Vanelzakker et al., 2014). A broad field of imaging studies concentrated on emotional regulation (e.g., Goldin et al., 2009b) and the automaticity and effectiveness of different regulatory strategies. Here, knowledge about the neural underpinnings helps to understand why patients engage in disorder maintaining behavior. Distraction from phobogenic stimuli, for example, is an often used avoidance strategy by anxious patients and leads to an attenuation of fear. On the neural level, mental distraction is characterized by a decrease in amygdala activation and an increase in prefontal functioning (Kanske et al., 2011), mirroring the release of fear patients might experience during avoidance. In contrast, cognitive reappraisal also leads to a decrease in amygdala activation but recruits a differential prefrontal network including more ventrally located brain regions (Kanske et al., 2011). However, in contrast to healthy subjects, this regulatory activation seems to be delayed in patients with SAD and encompasses fewer prefrontal areas. Although both groups showed an inverse correlation between the left dorsolateral prefrontal cortex and the amygdala, healthy subjects displayed similar correlational patterns in additional prefrontal areas (Goldin et al., 2009a).

Conclusions and Future Challenges

Clinical imaging studies have contributed to our basic knowledge and understanding of brain function in both single regions and functional networks in mental disorders. Although the neural markers of mental disease are still not clear and display a heterogeneous pattern across disorders, symptoms, and even between patients, they have supported psychobiological models and theories. During the past decades, neurobiological factors were increasingly accepted as etiological contributors to mental illness, thereby helping to minimize social stigmata associated with disorders such as schizophrenia and depression. In clinical practice, the explanation of metabolic and functional changes is nowadays often part of the treatment and increases patients' compliance to participate in either pharmacological or psychotherapeutic treatment.

However, the theoretical construct behind such research and the deliberate selection of appropriate methods are of particular importance. The theoretical conclusions regarding the underlying molecular or cellular processes depend on the imaging method. Likewise, experimental tasks can be differentiated according to the emotional and cognitive processes they are assumed to rely on. Typical studies in the field have focused on the processing of disorder-relevant stimuli, symptom provocation (*in vivo* and *in sensu*), or processes that are supposed to play a role in psychotherapy such as emotional regulation or extinction learning. Depending on the homogeneity of symptoms among patients with the same disorder, some disorders received more attention than others in previous research. Finding intelligent research designs for those disregarded psychopathological conditions represents a potential challenge for future research. Instead of mapping entire syndromes, the mapping of single symptoms by focusing on their underlying emotional or cognitive mechanisms seems more adequate. The systematic investigation of the neural correlates associated with a particular symptom that might be shared among different disorders and that might also be subclinically present among healthy individuals may lead to more specific neurobiological theories and might help to explain some of the controversial findings of past research. Future studies investigating factors that predict response to treatment or epidemiological factors such as genetic contributors and gene-environment interactions will further help to improve clinical treatment and the willingness to seek help. The finding of biomarkers, however, remains a huge challenge for future research. Until now, only a small percentage of the entire complexity of functional neural networks including their molecular, cellular, and structural underpinnings has been discovered but ongoing technical developments will provide additional sophisticated imaging methods to investigate the development, course, and recovery of mental disorders. The slow but increasingly adopted shift from the investigation of single neural modules to entire networks associated with particular types of processing may further help to unravel contradictory findings in the past. The use of specific symptom-related experimental tasks, presenting highly salient and specific stimulus classes, presumably signifies a first step toward this aim. In turn, the study of basic functions such as language or memory in patient groups represents an informative field of research also from a basic neuroscientist's perspective, providing important information about the fundamental neural mechanisms accompanying those processes. Determining the conditions under which a certain deviating neuronal pattern occurs may help to further elucidate common phenomena, such as hypofrontality, which can be observed across many patient groups with little specificity.

An often stated purpose of neuroimaging research is the aim to improve the early diagnosis and treatment of mental disorders. However, prospective studies in the field are rare because of the immense costs and efforts. It is also not clear, how a preventive treatment in those potential patients at risk should

look like. More reasonable, however, is the use of neuroimaging data for the prediction of treatment response: either psychotherapeutically, pharmacologically, or both. There is good evidence according to single studies (e.g., Siegle et al., 2006) but the reliability remains to be tested. Second, brain stimulation techniques rely on the exact determination of target regions in the brain. Likewise, neurofeedback and brain–computer interfaces (e.g., for severe neurological conditions) depend on clinical neuroimaging studies.

With the ongoing improvement of methods and analyzing techniques the knowledge about the neural correlates of mental disease will further contribute to the field of clinical psychology. The use of neuroimaging techniques may further help to disentangle the neural bases of the predispositions of mental disorders, their prodromal states, full-blown psychopathology, the course and treatment of these disorders, recovery, and the predicting factors of relapse. In the long run, imaging research in clinical psychology might be fundamental to provide reliable biological theories about mental illness thereby diminishing the social stigma associated with mental disorders and increasing patients' willingness to seek treatment.

Abstract

Imaging the neural changes that accompany psychotherapeutic treatment of mental disorders received increasing attention in recent years. Although the number of empirical studies in this field of research is relatively small, the informative value that can be gained from such studies is immense for both psychiatric neuroscience and evidence-based psychotherapy. This article gives an overview of important theoretical and methodological issues, discusses the potential mechanisms of action on brain level, and provides information about the present state of research and future directions for brain imaging research on psychotherapy-induced changes in neural functioning.

Introduction

In clinical psychology and psychiatric practice, psychotherapeutic interventions are often part of the standardized treatment approach for many of the mental disorders. Moreover, psychotherapy has been shown to be equally effective than or even superior to pharmacotherapy for many disorders and cases, but most often a combined treatment is recommended (Bandelow et al., 2007). Compared to pharmacological treatment, however, theoretical models of psychotherapeutic effects often lack a sufficient neurobiological basis. Whereas much research has focused on the neural correlates that accompany psychopathology, only little is known about the functional and structural changes that take place during psychotherapy-related recovery. During the past 20 years, however, an increasing amount of studies started to systematically assess the neurobiology behind evidence-based forms of psychotherapy such as cognitive-behavioral therapy (CBT) or psychodynamic theraphy by means of brain imaging techniques. Earlier studies primarily compared brain function before and after therapy by using imaging methods that enable the measurement of changes in overall brain metabolism such as positron-emission tomography (PET). With the increasing use of functional magnetic resonance imaging (fMRI) around the beginning of the new millennium, more and more studies investigated the specific functional activation changes that accompany information processing of disorder-related stimuli and tasks. However, there still exist relatively few studies leveraging functional and structural brain imaging techniques for the study of psychotherapeutic mechanisms. One of the foremost reasons for the sparse amount of studies in the field are the costs and efforts those studies bring about. Like pharmacological treatment studies, psychotherapy studies are quite time consuming and due to the face-to-face character of the treatment they require vast staff resources. Nevertheless, the informative value of such research for both clinical practice and neurobiological models of mental disorders is immense and warrants all of its efforts.

Understanding the Neurobiological Mechanisms Behind Psychopathology by Use of (Functional) Imaging Research

Psychopathology is linked to a range of functional impairments and sometimes also to structural reorganizations on brain level reflecting the disorder-related behavioral, emotional, and cognitive symptoms. Likewise, clinical improvement and recovery are accompanied by fundamental changes in behavior and subjective experience, which might in turn originate from neural modulations (Carrig et al., 2009). While the former (i.e., the acute disorder-related state) has been addressed by many neuroimaging studies, the neural correlates of clinical improvement lack sufficient neurobiological evidence despite the existence of several theoretical models. The missing biological foundation might in turn account for a range of prejudices against psychotherapeutic treatment in the general population, although there is plenty of evidence for the efficacy of cognitive-behavioral and psychodynamic therapy. However, understanding the neural correlates of psychotherapy and their effects on clinical improvement may not only help to increase compliance among patients but primarily serves for the testing and development of previous and future neurobiological and psychological models explaining the modulation of psychopathological behavior that takes place during psychotherapy and recovery (Linden, 2008; Etkin et al., 2005). Furthermore, the combination of brain and psychotherapy research allows for the detailed investigation of functional associations between single brain regions and certain clinical symptoms (Straube and Miltner, 2011). Even more, detailed information about the curative mechanisms of psychotherapy on brain level and the potential individual factors that either support or debilitate these effects can aid the selection of treatment, forecast of clinical improvement (Straube and Miltner, 2011; Linden, 2008; Roffman et al., 2005), or even lead to the development of new treatment protocols (Linden, 2008). Recent attempts in this area have been made by using neurofeedback, transcranial magnetic stimulation, transcranial direct current stimulation, or deep-brain stimulation to target and modulate brain regions associated with disorder-related symptomatology.

Also, the understanding of the complementing mechanisms behind the combined use of pharmacotherapy and psychotherapy on neural level may support the planning of individual treatment strategies, thereby preventing frustrating and time-consuming trial-and-error approaches (Roffman et al., 2005). Evidence exists, for example, showing that medication and psychotherapy affect partly the same and partly distinct brain areas in depressive patients (Martin et al., 2001). Others found that the degree of activation in one specific region

before treatment is associated with a better response to either behavior therapy or medication (Brody et al., 1998). Brain imaging, however, can help to disentangle the differential effects of both kinds of treatment, thereby providing important information for neurobiological processes that take place during recovery.

Because psychopathology is primarily associated with functional changes in neural information processing, especially functional imaging research may be helpful to identify biological markers of certain mental disorders or classes of symptoms which are common among several distinct disorders (e.g., avoidance behavior in anxiety disorders; Linden, 2008; Etkin et al., 2005).

Finally, imaging techniques may serve as an objective method to monitor progress during therapy, potentially even indexing the treatment duration and potential need for pharmacological add-on treatment that is necessary to achieve a satisfactory clinical outcome. On the contrary, they may also serve to detect and prevent potential relapses in advance (Etkin et al., 2005).

A summary of the aims and potential benefits of imaging research on psychotherapy is presented in **Table 1**. Taken together, previous and future imaging studies on psychotherapy and therapy-induced clinical improvement support and complement our understanding of psychopathology from early prodromal signs of illness to complete recovery of function. They may support interdisciplinary clinical practice and research between psychology and psychiatry by providing a neurobiological basis for psychotherapeutic effects, and they may further highlight the great potential of psychotherapy as an evidence-based treatment of mental disorders. The following sections provide an overview of the potential mechanisms of action on neural level, past experimental approaches and findings in the field, and the particular limitations and improvement opportunities for future research.

Mechanisms of Action

How can we determine if psychotherapy changes the brain and if so, what does that mean? In comparison to healthy control subjects, structural and functional alterations in brain activation have been found for many of the mental disorders that benefit from psychotherapeutic interventions such as mood disorders, anxiety disorders, or eating disorders. It seems reasonable that clinical improvement and an attenuation of disorder-related symptoms might in turn also be accompanied by functional or even structural changes on brain level, a process that is commonly referred to as neuroplasticity. If both the development of psychopathological symptoms and their remission are linked to neuroplastic processes, there are several potential mechanisms of how therapeutic interventions may affect neural functioning. On a macrolevel, improved symptomatology might result from a normalization of brain function, compensatory brain activation, or changes in functional connectivity (Linden, 2008; Straube and Miltner, 2011). Regarding the first, the simplest mechanism of action might be the 'reversion' of disorder-related functional, but also structural, alterations back to a 'normal' level that is undistinguishable from nonclinical samples. Overly increased prefrontal recruitment in patients with major depressive disorder (MDD), for instance, may return to nonclinical baseline levels over the course of treatment. According to this idea, the development of psychopathological symptoms is understood as a completely reversible process on both behavioral (symptoms) and physiological (brain) levels.

If the initial homeostasis may not be regained, compensatory processes may support and index clinical improvement. Instead of back-to-normal prefrontal functioning, the remission of depressive symptoms may be associated with compensatory increases or decreases in brain regions other than the disorder-related ones. In this view, disorder-related neural alterations are rather understood as a physiological trait instead of state of the temporarily present clinical symptoms. An efficient way to compensate for the functional impairment in certain brain regions might be the recruitment of other nonimpaired brain regions, a process which is often observed in patients with brain lesions and which might also apply to psychiatric patients.

According to a connectionist's view, therapy-related changes may not primarily take place in certain parts of the brain but rather in entire neural networks. There are, for instance, several studies showing deviations in functional connectivity between the amygdala and prefrontal cortex (PFC) for various anxiety disorders (Etkin et al., 2009; Kim et al., 2011). Functional connectivity, i.e., the joint or antagonistic interplay within one single or between two or more brain regions, is a direct result of neuroplasticity. Neuroplasticity in turn builds the basis for normal and pathological forms of learning, memory, and mental functions. In the context of the neural mechanisms of action underlying psychotherapeutic effects, improved symptomatology might thus result from neuroplastic changes on a microlevel, including the molecular, cellular, and systems level. On a molecular basis, the learning or relearning of certain stimulus–response associations, which is the principal

Table 1 Benefits of neuroimaging research on psychotherapy

Benefits for basic research	*Benefits for clinical practice*
Testing of theoretical constructs and models	Increase compliance
Identification of biological markers	Psychoeducation
Functional link between symptoms and neural structure	New treatment protocols
Conceptualization	Selection of treatment
Complementing effects of medication and psychotherapy	Prognosis and clinical outcome
	Prevention
	Monitoring progress

concept of behavior therapy, may induce functional or structural alterations in receptor systems, the synthesis and depletion of neurotransmitters, enzymes, ion channels, chromatin, or gene expression. On cellular level, clinical improvement may be accompanied by several pre- and postsynaptic processes but also by synaptogenesis or (hippocampal) neurogenesis. Particularly, the long-term potentiation (LTP) of particular projections, e.g., the top-down control of the PFC over subcortical limbic structures, may improve functional connectivity also in the long run thereby preventing future relapses. In contrast, long-term depression (LTD) can help to 'normalize' responses in brain regions that are assumed to react hyperactive or overly sensitive, as it has commonly been postulated for the amygdala and many anxiety disorders (Rauch et al., 2003; Etkin and Wager, 2007). On a systems level, a general reorganization of activation clusters and projections in gray and white matter may lead to improved functional connectivity following psychotherapy.

Taken together, there are several potential approaches to measure clinical improvement by means of functional or structural brain imaging (**Table 2**). Because the direct assessment of the effects on microlevel, particularly molecular and cellular changes, are difficult or ethically impossible to investigate in humans, most research in the field focused on indirect measures of molecular and cellular functioning primarily by the use of imaging techniques relying on metabolic indices of neural activity. Most evidence, however, comes from studies that elucidated therapy-induced changes on the systems level with a particular interest in the processes that are changing on the macrolevel, as mentioned earlier. Especially functional changes in disorder-related brain regions or functional connectivity between those areas have been studied in past research (e.g., Straube et al., 2006; Buchheim et al., 2012; Kircher et al., 2013). However, one has to keep in mind that the immediate effects of psychotherapeutic interventions or single sessions have never been studied so far. Most present evidence is related to measures that were conducted after the completion of therapy or, in rare cases, between single sessions (i.e., a case study of Schiepek et al., 2009). As a result, the neural findings from such studies are generally related to overall clinical improvement following psychotherapeutic treatment. In addition, online measures of brain activation during treatment are complicated and the standardization of such measures is virtually impossible. To reflect the immediate effects of certain therapeutic strategies (e.g., systematic desensitization or direct exposure), particular experimental designs may help to overcome methodological limitations and to gain a better understanding of the processes that may take place during according therapy sessions. Potential approaches for efficient past and future research are described in detail in the following section. To sum up, however, it is important to point out that psychotherapy by itself is very difficult to standardize. Even evidence-based manualized treatment varies between individual patients and therapists and depends on many individual factors such as present situation, symptoms, or coping strategies. The combination of such a nonstandardizable treatment on the one hand, and the aspirations of imaging research for a strict scientific and methodological practice on the other hand, has been a great challenge for past and will still remain a challenge for future studies.

Table 2 Potential effects of psychotherapy on molecular, cellular, and system levels and the according imaging techniques which enable the study of these effects

	Level				
			System		
	Molecular	*Cellular*	*Structural*	*Functional*	*Temporal*
Mechanisms of action (normalization, compensation, connectivity)	Receptor systems Synthesis/depletion Enzymes Ion channels Chromatin Gene expression	Pre-postsynaptic processes Neurotransmitter function Synaptogenesis Neurogenesis LTP and LTD	Reorganization Projections Clusters/modules Structure/volume Gray matter White matter	Reorganization Projections Cluster modules Functional connectivity	Temporal processing
Methods	PET SPECT	PET EEG	PET MRI CT	PET fMRI fNIRS EEG MEG	EEG MEG (fMRI) (fNIRS)

ASL, arterial spin labeling; CT, computed tomography; DTI, diffusion tensor imaging; EEG, electroencephalography; ERP, event-related potential; (f)MRI, (functional) magnetic resonance imaging; (f)NIRS, (functional) near-infrared spectroscopy; FFT, fast Fourier transformation; LTD, long-term depression; LTP, long-term potentiation; MEG, magnetoencephalography; PET, positron-emission tomography; rCBF, regional cerebral blood flow; SPECT, single-photon emission tomography; VBM, voxel-based morphometry; methods that are presented in parentheses are less suited but still able to infer valuable information.

Studying the Neural Correlates of Psychotherapy

A common way to investigate neural changes related to psychotherapy includes at least either a pre–posttreatment comparison or the posttreatment comparison of a treatment group to a comparable control group (e.g., patients on a waiting list). A combination of both strategies is obviously advantageous: First, because the former cannot control for effects of time (e.g., potential habituation effects to the measurement procedure), and second, because the latter provides only little information about treatment-related changes and may reflect only general trait-related differences between groups in case of a healthy control sample. The experimental approaches regarding time points of measurement, psychotherapeutic treatments, control groups, methods, and experimental tasks vary from study to study.

With respect to time, the majority of studies decided for a pre–post design (e.g., Straube et al., 2006) while others included also intermediate (Schiepek et al., 2009) and follow-up measurements (Schienle et al., 2009). Treatments mostly referred to evidence-based forms of psychotherapy such as (cognitive) behavioral (CBT) and psychodynamic therapy or related therapeutic strategies such as behavioral activation (Dichter et al., 2010) or interpersonal therapy (IPT) (e.g., Brody et al., 2001; Martin et al., 2001), respectively. Apart from those general treatment approaches, there are also studies that investigated other specific forms of therapy such as eclectic behavioral therapy (Lindauer et al., 2008) and eye movement desensitization and reprocessing (EMDR; Levin et al., 1999) which are particularly tailored to patients with posttraumatic stress disorder (PTSD), systemic couple treatment (Schiepek et al., 2009), neuropsychological and cognitive remediation treatment for schizophrenic patients (e.g., Wykes et al., 2002), or sleep deprivation as an antidepressive treatment (Gillin et al., 2001).

Regarding the selection of one or more control groups, several options exist which in turn influence the informative value that can be drawn from the results. A great deal of studies included a healthy control group which particularly allows for the investigation of 'normalization' processes following psychotherapy. Other studies compared the treatment group to patients who received no treatment between the time points of measurement (e.g., patients on a waiting list; Furmark et al., 2002; Straube et al., 2006) or received psychopharmacological medication as an alternative treatment (e.g., McClure et al., 2007; Furmark et al., 2002). A third possibility is the post hoc comparison of treatment responders and nonresponders (Furmark et al., 2002). Generally, the inclusion of a patient control group seems recommended to control for potential overall disorder-related alterations in brain metabolism which may confound the results. There are only few studies including both a patient control group and healthy subjects.

The variety of available functional and structural imaging methods offers a multitude of possibilities to study the effects of psychotherapy on the brain. The selection of methods depends, however, pretty much on the particular research questions and hypotheses at hand (**Table 3**). Structural imaging techniques such as MRI are particularly suited to investigate whether morphological between-subject differences can predict later treatment responses. It has been shown, for instance, that PTSD patients who benefitted from CBT had larger rostral anterior cingulate cortex volume before treatment than nonresponders (Bryant et al., 2008b). Until now, however, most research concentrated on treatment effects on the overall metabolic activity or functional activation in certain disorder-related brain regions using PET and fMRI, respectively. Variations in regional cerebral blood flow (rCBF) were mostly assessed by means of PET, only a minority of studies used other methods such as computerized tomography (CT; Nakatani et al., 2003) or single-photon emission tomography (SPECT; Martin et al., 2001; Lindauer et al., 2008). For the investigation of neural changes in information processing following psychotherapy, fMRI has been the method of choice for most studies. In addition, fMRI allows for specific analyses regarding functional connectivity and the predictive value of pretreatment brain responses in disorder-related brain regions.

Table 3 Overview over neuroimaging and electrophysiological methods suited for the study of psychotherapy effects

Technique	*Spatial resolution*	*Temporal resolution*	*Potential research questions*	*Example study*
MRI	Relatively high	N/A	Morphology Volume	Bryant et al. (2008b)
CT	Moderate/high	N/A	Morphology Volume	Nakatani et al. (2003)
SPECT	Moderate	Very low	Metabolism	Lindauer et al. (2008)
PET	Moderate	Very low	Metabolism	Furmark et al. (2002)
fMRI	High	Moderate	Connectivity Functional activation Regional activation	Straube et al. (2006)
fNIRS	Fair	Moderate	Functional activation Regional activation	N/A
MEG	Low	Very high	Temporal processing Lateralization	Adenauer et al. (2011)
EEG	Poor	Very high	Temporal processing Lateralization	Thase et al. (1997)

CT, computed tomography; EEG, electroencephalography; (f)MRI, (functional) magnetic resonance imaging; fNIRS, functional near-infrared spectroscopy; MEG, magnetoencephalography; PET, positron-emission tomography; SPECT, single-photon emission tomography.

Surprisingly, until now imaging research on psychotherapy focused exclusively on those relatively expensive methods, which are partly accompanied by undesirable side-effects due to radiation (i.e., PET and SPECT), although there are a range of more convenient measurement techniques such as electroencephalography (EEG) or functional near-infrared spectroscopy (fNIRS). Actually, to date there exist relatively few electrophysiological studies in this field of research, although the high temporal resolution of such methods (e.g., EEG or magnetoencephalography (MEG)) allows for a far more detailed insight into the temporal characteristics of information processing when compared to methods that rely on hemodynamic (i.e., fMRI) or metabolic activation (i.e., PET).

In contrast to resting state measures, the performance of experimental tasks allows for a better control of the mental processes underlying the according brain scans. Depending on the task, specific aspects of information processing and how this processing is affected by psychotherapy can be studied. Here, previous experiments predominantly focused on activation changes to disorder-related stimuli or tasks, following exposure or symptom provocation. Also the general theoretical foundations of certain treatments can be mapped on brain level to gain an even more detailed insight into the particular processes that are assumed to accompany psychotherapy. More specifically, experiments on fear conditioning and particularly fear extinction, for instance, may reflect maintaining factors of symptomatology and the effects of exposure therapy on brain level in patients with anxiety disorders (e.g., Kircher et al., 2013).

All in all, the selection of methods and experimental design determines what informative value can be drawn from imaging studies on the treatment effects of psychotherapy. The planning and realization of such studies is accompanied by considerable costs and efforts. On the other hand, this kind of research offers an invaluable opportunity to monitor how psychotherapy, and thus cognitive and emotional restructuring of information processes, affect the brain in a limited time interval. Furthermore, research on psychotherapy may provide insight into the supporting and debilitating neural factors impacting on treatment responses and as such therapy success.

Status Quo

The first studies that compared pre- and posttreatment changes in cerebral metabolism date back to the early 1990s. Since then, most research focused mainly on MDD and anxiety disorders with the largest number of studies investigating patients with obsessive–compulsive disorder (OCD; **Figure 1**). Only a limited amount of data are available for patients suffering from schizophrenia or eating disorders and there are only single studies on other disorders (e.g., chronic fatigue syndrome: de Lange et al., 2008; or alcohol dependence: Feldstein Ewing et al., 2011). In the following, two lines of research are presented to exemplify how imaging techniques help to understand the impact of psychotherapy on the neurobiology of psychopathology, such as depression or anxiety. An overview of the amount of studies on various forms of psychotherapy and with respect to the type of imaging method is displayed in **Figure 1**. More specific information about existing studies, their experimental designs, and findings is presented in **Table 4**.

Major Depressive Disorder

Studies on psychotherapy effects on brain activation in MDD patients observed functional alterations or overall metabolic changes primarily in prefrontal cortical regions. Following psychotherapy, activation decreases were found in widespread prefrontal areas including dorsolateral, ventral, orbitofrontal, and medial PFC (Buchheim et al., 2012; Goldapple et al., 2004). Furthermore, alterations were consistently observed

Figure 1 Number of imaging studies with respect to type of psychotherapy and imaging technique. Both figures indicate the number of imaging studies on the treatment of different psychopathological conditions. The left panel shows how these studies divide into those that included a behaviorally oriented psychotherapeutic treatment and those which applied a rather psychodynamically oriented form of therapy. Behavioral treatment mainly referred to (cognitive-) behavior therapy or related techniques, psychodynamic theraphy mostly referred to interpersonal therapy. The right panel displays the use of different imaging techniques in relation to the disorder of interest. Functional methods referred exclusively to functional magnetic resonance imaging, metabolic techniques included positron-emission tomography and single-photon emission tomography, temporal methods referred to electroencephalography and magnetoencephalography, and structural methods included magnetic resonance imaging and computed tomography. Studies were selected based on a literature search in relevant databases by using combinations of keywords including a specific disorder and '(psycho-) therapy,' 'CBT,' 'behavior therapy,' or 'psychodynamic.' ED, eating disorder; MDD, major depressive disorder; OCD, obsessive-compulsive disorder; PD, panic disorder; PTSD, posttraumatic stress disorder; SAD, social anxiety disorder; SP, specific phobia; SZ, schizophrenia; Other: alcohol dependence, chronic fatigue syndrome, generalized anxiety disorder.

Table 4 Overview of experimental designs and main findings of imaging studies on anxiety disorders, depression, and schizophrenia

	Anxiety disorders	*Depression*	*Other*
Disorders or predominant symptomatology	OCD SP PTSD PD SAD GAD	MDD Depressive episode	Schizophrenia Eating disorders Chronic fatigue Alcohol dependence[a]
Type of task	None (structural) Resting state Symptom provocation Exposure Emotional processing Fear conditioning Memory Subliminal processing Executive functions	Resting state Sleep Emotional processing Executive functions	None (structural) Self-perception Executive functions Working memory
Posttherapy (main findings)	Decreased: limbic system, OFC and caudate nucleus (OCD) Increased: PFC, connectivity between PFC and limbic and paralimbic areas	Activation changes: limbic system, PFC (ACC, mPFC, and DLPFC)	Increased: PFC (schizophrenia), PFC volume (chronic fatigue) Activation changes: extrastriate body area (eating disorder)
Predictors	OFC (OCD), visual cortex (SAD), ACC volume (PTSD), superior temporal and superior/middle frontal gyrus (PTSD)	vmPFC, DLPFC, anterior temporal lobe, abnormal EEG sleep profile	Schizophrenia: DLPFC and DLPFC-cerebellum connectivity, PFC, thalamus, precuneus

ACC, anterior cingulate cortex; DLPFC, dorsolateral prefrontal cortex; ED, eating disorder; EEG, electroencephalography; GAD, generalized anxiety disorder; MDD, major depressive disorder; mPFC, medial prefrontal cortex; OCD, obsessive-compulsive disorder; OFC, orbitofrontal cortex; PD, panic disorder; PFC, prefrontal cortex; PTSD, posttraumatic stress disorder; SAD, social anxiety disorder; SP, specific phobia; vmPFC, ventromedial prefrontal cortex.
[a]This study examined situational aspects of motivational interviewing and not directly therapy-related neural changes. Therefore, results are not included.

across studies in cingulate cortex or neighboring regions such as subgenual or para-cingulate cortex (Martin et al., 2001; Siegle et al., 2006; Dichter et al., 2010). Neural treatment responses were also found to vary between psychotherapeutic and psychopharmacological interventions. Whereas both treatments caused increased basal ganglia activity, IPT affected also cingulate areas while antidepressant medication led to activation increases in temporal areas (Martin et al., 2001). Other studies found diverging effects between pharmacotherapy and psychotherapy within medial PFC or laterality of effects (Brody et al., 2001; Goldapple et al., 2004). Apart from resting state, clinical improvement following psychotherapy was associated with functional changes in the respective prefrontal regions and decreases in amygdalar and hippocampal activation (Buchheim et al., 2012; Dichter et al., 2010; Fu et al., 2008).

Anxiety Disorders

Anxiety disorders are particularly suited to investigate therapy-induced changes in information processing of anxiety-related stimuli because symptoms can be elicited relatively easily by exposing the patient to fear-provoking stimuli. Confronting spider phobics with videos sequences of spiders, for instance, led to profound activation of the fear network in comparison to healthy controls. Following CBT, activation in those areas (i.e., anterior cingulate cortex (ACC) and insula) decreased profoundly in contrast to patients assigned to a waiting-list group (**Figure 2**; Straube et al., 2006). Because exposure or systemic desensitization are core CBT techniques for many anxiety disorders, symptom provocation studies exposing subjects either directly or indirectly to fear-provoking stimuli allow for a deeper view on the underlying neural processes of abnormal information processing which are present before treatment and how these processes are affected by psychotherapy. Depending on the particular disorder and symptomatology at hand, the degree of exposure between such studies varied from exposure *in sensu* (i.e., imagery or recall of traumatic events in PTSD; Levin et al., 1999; Lindauer et al., 2008) to exposure *in vivo* (i.e., public speaking task for patients with social anxiety disorder; Furmark et al., 2002). To date, the number of imaging studies on psychotherapy effects on anxiety disorders clearly outweighs those focusing on other disorders such as mood or eating disorders (**Figure 1**). Here, OCD has been the most extensively studied disorder followed by studies on PTSD and specific phobia, whereas only few studies investigated panic disorder and social anxiety disorder. As yet, there is only a singly pediatric study on generalized anxiety disorder (GAD; McClure et al., 2007).

With respect to the mechanisms of action, many studies on OCD found activation changes toward a 'normalized' level following psychotherapy in the orbitofrontal cortex (OFC) and striatum (Freyer et al., 2011; Nabeyama et al., 2008). Particularly, activation in the caudate nucleus decreased after successful treatment and the degree of change in both OFC and caudate nucleus was related to the treatment response (e.g., Brody et al., 1998; Nakatani et al., 2003). Overall, functional and resting state activation of the frontostriatal

Figure 2 Psychotherapy effects on anterior cingulate cortex (ACC) and insula in a group of spider phobics. The figure displays activation in anterior cingulate cortex (ACC; left panel) and insula (right panel) to phobic stimuli in spider phobics before and after cognitive-behavioral theraphy. Compared to the waiting-list group (WG) and compared to the first scanning session, the therapy group (TG) showed significant reductions in activation in both areas following treatment during the second scanning session. The figure has originally been published in a functional magnetic resonance imaging study performed by Straube, T., Glauer, M., Dilger, S., Mentzel, H.J., Miltner, W.H., 2006. Effects of cognitive-behavioral therapy on brain activation in specific phobia. Neuroimage 29, 125–135 and is reproduced with kind permission from Elsevier (© 2006 Elsevier Inc. All rights reserved).

network was found to be attenuated following behavioral therapy (Baioui et al., 2013).

Overall, anxiety disorders that are primarily associated with an overactivation of the fear network, mainly of the amygdala, were found to exhibit decreased recruitment of those areas following psychotherapy (e.g., Furmark et al., 2002). Moreover, after therapy, regulatory prefrontal regions such as the OFC and ACC were activated more strongly (Schienle et al., 2009; Bryant et al., 2008b; Levin et al., 1999). In contrast, PTSD patients who responded poorly to CBT displayed greater amygdala activation to fearful faces at baseline (Bryant et al., 2008a). Also, functional connectivity within the fear network and particularly fear-regulating prefrontal regions increased after therapy (Kircher et al., 2013).

Taken together, it was shown that psychotherapy affects neural functioning in anxiety disorders through activation of all three suggested mechanisms of action. Following therapy, responders displayed attenuated activity in formerly hypersensitive limbic regions (normalization), additional recruitment of regulatory prefrontal areas (compensation), and increased overall connectivity between both limbic and top-down brain regions (functional connectivity).

Past Challenges and Future Directions

Conducting imaging studies along the course of psychotherapeutic treatment definitely poses a challenge with respect to costs and efforts. The combination of repeated measures designs and clinical samples is relatively time consuming and the high risk of drop-outs during treatment represents an additional challenge. In addition, the selection of a proper control group can be difficult due to ethical constraints. Randomly assigning patients to a waiting list in order to control for treatment effects clearly represents a drawback for those patients and holds the risk of a potential aggravation of symptoms. On the other hand, in clinical practice, patients are often put on a waiting list until they can start psychotherapeutic treatment and this waiting time most often exceeds that of a controlled clinical treatment study. Depending on the disorder and severity of symptoms, however, this proceeding might be inappropriate thereby probably excluding those subjects with the most distinct symptoms in experimental designs. For disorders that are accompanied by such severe symptoms that do not allow for the postponement of treatment (e.g., severe forms of MDD) the comparison of two or more evidence-based psychotherapies represents a valuable alternative. Nevertheless, the informative value of studies with a waiting list design definitively warrants their costs and efforts in contrast to those including a nonclinical control group.

The results of previous studies on the neural correlates of psychotherapy have shown the diversity of mechanisms through which neural functioning is affected by psychotherapeutic treatment of anxiety disorders. Similar widespread effects are conceivable for other disorders and highlight the need for further and extended research on disorders that particularly benefit from psychotherapy such as mood and eating disorders. Studies with larger sample sizes, sophisticated experimental designs, and high levels of standardization may help to better understand the functional and structural neural processes that accompany positive treatment outcomes. A recent study on panic disorder refined these experimental demands by the inclusion of a very large sample size in comparison to earlier studies, manualized treatment, and

functional imaging of specific impaired aspects of information processing (Kircher et al., 2013). In addition to such manual-based treatment, group therapy may further help to increase within-subjects comparability and to lower costs and efforts of future research.

Despite the substantial amount of existing studies, there are still a lot of opportunities for future studies particularly regarding methods and clinical populations. Apart from the lack of studies on disorders other than MDD and anxiety disorders, only single studies (e.g., Huyser et al., 2011; McClure et al., 2007) focused on children or adolescents although particularly the younger brain is much more plastic due to developmental processes. Research methods which can be performed in a more natural setting and are free of side effects (e.g., EEG) might help to investigate such potentially more sensitive subjects. Overall, electrophysiological research in this field is scarce but may provide much more detailed insight into the temporal characteristics of how information processing is affected by psychotherapy. The combined use of methods with high temporal and high spatial resolution is even more tempting and the ongoing refinement of analyzing techniques may stimulate future research.

Because only a portion of the existing studies investigated functional activation in response to specific tasks and stimuli, much more research is needed to elucidate how various aspects of disorder-related stimulus processing such as explicit vs implicit or subliminal vs supraliminal emotional processing are modulated over the course of therapy. Furthermore, symptom provocation studies (e.g., exposure or anticipation of disorder-related stimuli and symptoms) provide direct information about the neural correlates that accompany clinical improvement. New research and treatment methods such as exposure by means of a virtual reality environment even allow for online neurophysiological measures during single therapy sessions (Wiederhold and Wiederhold, 2008). In the long run, follow-up studies may then test whether the degree of activation changes in certain areas predict better clinical outcome.

Overall, the investigation of psychotherapy-related alterations in brain activation still offers a multitude of open questions to answer. Future research should therefore particularly aim to disentangle the neural factors that predict the treatment response to individual therapies and clinical outcome. These studies may in turn help to select the appropriate therapy and number of sessions to meet the patient's individual needs, thereby minimizing the risk of drop-outs and later relapses.

Conclusion

Thus far, existing imaging studies have shown that psychotherapy significantly affects neural and metabolic functioning in a range of mental disorders with most evidence for MDD and anxiety disorders. Particularly, the recovery from anxiety-related psychopathology has been extensively studied by means of different experimental designs and imaging techniques, demonstrating that clinical improvement is associated with several neural processes. The potential mechanisms of action that have been identified so far include a normalization of activity, compensatory recruitment of regulatory brain regions, and increased connectivity within disorder-related neural networks, but also more general processes such as neuroplasticity are strongly linked to the fundamental ideas of particular therapies such as CBT.

Generally, it is important to keep in mind that the neural correlates of psychotherapy are not directly measurable since treatment and clinical improvement represent processes that take more time than a single experimental measurement session. Pre- and postmeasures of single therapeutic sessions or even an entire therapy can only provide insight into the neural changes that accompany the multitude of mechanisms that are activated by psychotherapy. These mechanisms are in turn dependent on the type of therapy and may not be uniform across patients and disorders. Imaging studies on psychotherapeutic effects, whether in general or focusing on specific therapeutic strategies, however, can provide valuable information about the underlying neural substrates of psychopathology and how these substrates are changing from acute illness to complete recovery of function. More detailed insight into the effects of particular therapeutic strategies can be obtained from experimental designs that aim to mirror the psychological processes that occur during single therapeutic sessions (e.g., experiments on extinction learning for the investigation of neural processes that take place during exposure sessions).

Although the number of studies in the field is still relatively small, previous research has given a promising impression of the numerous possibilities with respect to experimental design, hopefully stimulating future research. In the long run, such research may lead to individualized treatment protocols and better prevention of nonresponses, dropouts, and remission of symptoms.

Imitation during Infancy and Early Childhood

Rebecca A Williamson, Georgia State University, Atlanta, GA, USA

Abstract

Imitation is an efficient way for infants and young children to benefit from others' knowledge. By copying observed acts, children learn novel behaviors for interacting with their environment and they establish interactions with social partners. This article provides an introduction to the development of imitation by reviewing what components of behaviors children are able to imitate at different ages. Then, this article explains how functional and social factors regulate when children take up others' examples through imitation. Throughout, theoretical and practical examples illustrate the interdisciplinary nature of imitation research.

Others' acts are a repository of accumulated human knowledge. Consider watching someone preserve food after a harvest. The canner will examine each vegetable for size and ripeness, use tools and specific behaviors to chop them, and measure and combine ingredients to achieve a desired taste. Carefully copying each behavior can have multiple benefits. For example, copying how the canner boils glass jars will reduce the risk of food contamination and of getting burned. Observational learning and imitation specifically saves a learner from the painstaking (and sometimes dangerous) process of trial and error learning (Bandura, 1977). It allows a learner to take advantage of the knowledge hard-won by past generations.

This article provides an overview of research on young children's imitation, i.e., copying others' acts. I begin with a description of the development of imitation through infancy and into the toddler and preschool years. This article highlights formative findings in research on social learning and provides a timeline of developments in what children imitate from a behavior. The second section describes the flexibility of imitation with a review of the functional and social considerations that influence children's learning.

Throughout this article, I provide implications of imitation research, with the goal of illustrating the breadth of this field. Imitation is readily observable, making it an important research tool. Studies of imitation contribute to basic theoretical debates, such as understanding what is unique about human learning. This basic research also has practical implications, including identifying efficient educational and clinical practices.

Imitating Components of Action

Neonatal Imitation

From their first days, infants reproduce simple body acts. In a seminal study, neonates (aged 12–21 days) saw an adult produce a distinctive movement (Meltzoff and Moore, 1977), such as a tongue protrusion. Then, the adult assumed a passive expression. During this test period, infants were more likely to reproduce the body movement that the adult had most recently shown (e.g., tongue protrusion) versus other target acts (e.g., mouth opening). Children also showed more target acts after seeing the adult produce the target act versus in baseline trials where the adult only ever showed a passive face. Both of these comparisons indicate imitation.

Many subsequent studies have replicated these findings (for review, see Meltzoff and Moore, 1997). One tested infants that were less than 72 h old (Meltzoff and Moore, 1983), with children who had never looked in a mirror or seen pictures of themselves. They also had never been reinforced for copying behaviors. The fact that these infants matched the adult's facial movements suggests an innate mapping between one's own and others' bodies.

Immediate and Deferred Imitation of Acts on Objects

Over the course of the first year, infants' engagement with objects increases (Bakeman et al., 1990), and their imitation parallels these developments. From the age of 6 months, infants imitate simple acts on objects (Barr et al., 1996), such as removing and shaking a puppet's mitten. Over the next year and a half, children become better able to imitate more acts and to maintain the temporal sequence in which acts are demonstrated (Bauer and Mandler, 1989, 1992).

From 6 to 12 months of age, infants also begin to imitate acts after substantial delays. To test this *deferred imitation*, children observe a model produce target acts on objects. After a delay, children are given the objects, and their production of the target acts is scored. Control groups can include different children who do not see an adult act on the materials (a baseline control) or who see an adult manipulate the materials in a different way (an object manipulation control). Using such procedures, researchers have demonstrated that infants aged 6–12 months can remember and reproduce acts after a 24 h delay (Barr et al., 1996; Collie and Hayne, 1999). By age of 14 months, infants remember multiple novel acts after 4 months (Meltzoff, 1995a). Increasing the number of demonstrations or the amount of viewing time improves deferred imitation (e.g., Barr et al., 1996, 2007a,b).

Implications for Theory

Deferred imitation has been important for developmental theory. For one, reports of deferred imitation challenge Piaget's (1962) seminal theory of cognitive development. Because deferring imitation involves the ability to mentally represent actions, Piaget thought it should arise between the

ages of 18–24 months. The clear evidence for deferred imitation in much younger children supports proposals that Piaget underestimated infants' cognitive abilities (Meltzoff, 1988a).

Deferred imitation is also important for considering what neural processes might underlie imitation. Certain cells in the premotor cortex of monkeys have been shown to fire when an act is either observed or produced (di Pellegrino et al., 1992; Rizzolatti et al., 1996); these cells react, for example, both when a monkey reaches or sees another individual reach. Thus, these *mirror neurons* create a link between self and other in the brain. One very simple way that mirror neurons could underlie imitation is for the observation of an act to automatically elicit the same motor program and lead the observer to produce the act (Rizzolatti et al., 1999). However, the delays involved in deferred imitation studies do not support this most basic mechanism. Neuroscientists continue to generate and test more complex neural accounts for imitation (e.g., Huber et al., 2009; Marshall et al., 2011; Paulus et al., 2013; Reid et al., 2011).

Imitation of Subgoals and Means

Many studies of imitation involve causing physical changes to objects, such as turning on lights or opening boxes. This emphasis on outcomes is understandable; infants are more likely to reproduce acts that produce observable effects versus those that do not (for review, see Elsner, 2007). However, young children imitate more than physically effective acts. In one demonstration of this, 14-month-olds saw an adult turn on a light using a touch panel (Meltzoff, 1988a). Instead of reaching out with his hand, the adult bent and touched the panel with his head. When allowed to act, two-thirds of the children also imitated the unusual bending action they had seen the adult use to illuminate the light. Thus, their imitation included the demonstrated outcome as well as the adult's method for producing the result.

Implications – Theories of Human Learning

The distinction between copying outcomes and means has proven important for distinguishing human and nonhuman social learning (for review, see Want and Harris, 2002). Children readily copy the specific means that others use. In fact, they imitate even causally irrelevant acts, a phenomenon called 'overimitation' (e.g., Horner and Whiten, 2005; Lyons et al., 2007; McGuigan et al., 2011). In contrast, although folk wisdom tells us that 'monkey see, monkey do' – really, monkeys don't. Carefully controlled studies show limits in nonhuman primates' social learning relative to humans' (for review, see Whiten et al., 2004). Specifically, nonhuman primates are less likely to copy others' specific means (e.g., Nagell et al., 1993; Whiten et al., 1996).

Imitation may be crucial for the development of complex culture (Boyd and Richerson, 1996; Meltzoff, 1988b; Tomasello, 1999). One account is that imitation is a mechanism that holds behaviors in place within a community (Tomasello, 1999). The idea is that individuals will sometimes innovate; an inventor might devise a new food processing technique. With imitation, that innovation will spread quickly to other members of the group. Thus, if the inventor dies, the innovation is not lost to the community. Imitation should also improve progress within a group. Effective social learning will lead more individuals to use the advanced behavior, and each may enhance it with new innovations.

Peer-to-peer learning studies illustrate the power of imitation for transmitting information within groups (Flynn and Whiten, 2008; Horner et al., 2006; Nielsen et al., 2012a). One procedure, called chain diffusion, is essentially a game of telephone – information is passed through a group, with each learner becoming the teacher for the next individual. These studies show impressive imitation among peer groups, with some target acts maintained across chains of up to eight 3-year-olds (McGuigan and Graham, 2010). These studies illustrate the plausibly of imitation as a mechanism for the efficient spread of information through communities.

Imitating Inferred Goals

Both the outcomes produced and the means used to attain those outcomes are observable from others' behaviors. However, young children's imitation is not bound to what they can see. Children also infer and imitate the goals underlying behavior. In one experiment, 18-month-olds saw an adult try, but fail, to complete acts with objects (Meltzoff, 1995b). For example, the adult pulled at the ends of a barbell toy, but never separated the two pieces. When given the objects to manipulate, children who saw the failed demonstration were as likely to produce the intended outcome as were children who saw the adult complete the act. Thus, children did not imitate the observed surface behaviors; they were not limited to slipping their fingers from the toy. Instead, 18-month-olds inferred and reproduced the intentions underlying the behaviors. Even younger children imitate the goals underlying simple acts. For example, 7-month-olds will selectively reach for an object that an actor previously tried, but failed, to reach (Hamlin et al., 2008; see also Bellagamba and Tomasello, 1999).

Children's ability to infer intentions depends on the identity of the actor. Meltzoff (1995b) contrasted two different unsuccessful attempts at the barbell-pulling task. One group of children saw a human actor fail to pull apart the object, as described above. A second group saw a machine grip the barbell with two pincers. The pincers slid from the edge, to recreate the adult's unsuccessful attempts. Children who saw the adult were significantly more likely to pull apart the object than were children who saw the machine perform the carefully matched acts. Thus, children attributed intentions to the person, but not the mechanical pincers.

Modifications of this imitation paradigm have helped to identify when children classify actors as agents (with goals and intentions) versus nonagents. For one, children are unlikely to imitate the unfulfilled goals of actors that have little similarity in body morphology to humans, such as machines and boxes (Slaughter and Corbett, 2007; Johnson et al., 2001; Mahajan and Woodward, 2009). However, young children will imitate intermediate actors (e.g., puppets or robots) that have human-like physical characteristics, such as a face and arms (Itakura et al., 2008; Johnson et al., 2001). A second factor that influences the imitation of unfulfilled goals is social cues to animacy. When a human confederate engages a nonhuman actor as if it is animate (e.g., naming it, waving to it), children are more likely

to imitate it (Johnson et al., 2001). When the actor responds contingently to a human confederate, imitation is also boosted (Itakura et al., 2008). Understanding how agency is inferred contributes to our understanding of what representations underlie subsequent theory of mind development (Johnson, 2003).

Imitating Inferred Strategies

In addition to inferring the general goal underlying others' acts, children can also reproduce the *rules or strategies* that guide others' behaviors. This is a way that adults may commonly use observational learning; Studying the way a good speaker presents information can be as informative as the content of the talk. One type of abstract information that children learn through imitation is the temporal order of an action sequence (Subiaul et al., 2007a,b). Preschoolers who saw an adult press series of pictures in a particular order on a touch screen (like entering an ATM pin code) needed fewer trials to input the same sequence than did children who had to learn through trial and error. Importantly, the location of the pictures varied between each trial. This meant that the children had to learn the order in which to press the pictures, not the adult's motor movements.

Preschoolers also imitate the hierarchical organization that structures action (Flynn and Whiten, 2008; Whiten et al., 2006). In these tasks, children watched an adult assemble and use a series of keys to unlock a box and retrieve a reward. The adult either assembled and used one key before moving to the next key, or he completed one assembly step with all of the keys before moving to the next step. The children maintained the adult's hierarchical strategy when opening the box themselves; e.g., children who saw the adult take a stepwise approach also completed each step in turn.

Children also imitate abstract sorting rules from others' behaviors (Williamson et al., 2010). In one experiment, children saw an adult sort a set of objects into two piles based on their colors. Children were given a chance to sort the same objects and a second set of objects. The second set included different kinds and colors, and the adult never sorted them. This set was used to test whether children would generalize the sorting rule. Three control groups were used to pinpoint the critical elements of a demonstration for promoting sorting. In the most stringent control, the adult brought out the objects presorted by color, picked up each object, and returned each to its starting location. These behaviors were carefully matched to the experimental group, except the adult never sorted the objects.

The first finding from this experiment was that children who saw the adult's sorting behaviors were more likely to reproduce the color sorting strategy than were children in the control groups (see **Figure 1(b)**). Sorting behaviors were critical for eliciting imitation. Closely matched demonstrations that did not include sorting did not prompt children to imitate. A second finding was that children who saw the adult's sorting behaviors applied the color sorting rule to the second set of object, even though they were not shown what to do with those objects. This illustrates an important benefit of imitating abstract strategies and rules. Unlike specific behaviors on objects, rules are generalizable across materials and situations.

Interim Summary

During the first few years of life, children's imitation advances in complexity. From reproducing body movements and acts with objects, children progress to copying more complex sequences of acts and specific means used to attain outcomes. Children also infer and imitate the goals and rules that guide overt behaviors. Examinations of what children can imitate have contributed to our understanding of how human social learning compares and contrasts to the social learning of other primate species. These examinations have also helped chart the development of memory (e.g., Bauer et al., 2000) and early theory of mind (Carpenter et al., 1998; Meltzoff, 1995a). With this developmental timeline as a foundation, this article now turns to what regulates children's imitation.

Regulating Imitation

Functional Considerations

Although children can reproduce many elements of a demonstration, they are not bound to imitate. A substantial body of research indicates that children use imitation flexibly. Uzgiris

Figure 1 Imitation of an abstract rule. (a) One set of materials used to assess children's imitation of a sorting strategy. (b) 36-month-old children showed elevated rates of sorting by color only after witnessing an adult's sorting demonstration. From Williamson, R.A., Jaswal, V.K., Meltzoff, A.N., 2010. Learning the rules: observation and imitation of a sorting strategy by 36-month-old children. Developmental Psychology 46 (1), 57–65, reprinted with permission.

(1981) thought one reason to imitate is to learn how to do new things. If so, an efficient imitation strategy may be to reproduce the overall outcome of a demonstration, but to exclude acts that may reflect personal style (Williamson and Markman, 2006). In contrast, if the purpose of a behavior is not clear, imitating in precise detail may be beneficial; copying even subtle means will improve the likelihood that the imitator will reproduce the demonstration's critical elements.

Several experiments show that when acts lead to a clear outcome, children are less likely to copy others' precise means (Bekkering et al., 2000; Carpenter et al., 2005). In one, 3-year-olds saw a model place an object on a mat using a distinctive series of acts (Williamson and Markman, 2006). For example, she used two fingers to place a penlight horizontally, and then rotated the light so that it was oriented vertically relative to the child. One group saw only this unusual behavior. In a second group, the adult provided a reason for the placement of the light. After using the unusual acts to place the object, she added extra pieces so the penlight formed the stem of a flower. Those children who saw the extra pieces reproduced fewer of the adult's distinctive acts (e.g., the two-fingered grip, the rotating) relative to children who did not have this context provided.

Another factor that influences children's imitation is the efficacy of the means leading to specific ends. When means are shown to be ineffective, children are less likely to imitate that strategy (Nielsen, 2006; Want and Harris, 2001). Additionally, when children themselves have difficulty attaining an end using their own approach to a task, they are more likely to precisely imitate the means another used to complete the task (Pinkham and Jaswal, 2011; Harnick, 1978; Schulz et al., 2008). In one demonstration, 36-month-old children were given experience with a straightforward task – for example, they were told to open a drawer to retrieve a toy (Williamson et al., 2008). In one group, children could simply pull open the drawer. For the other group, however, the task was rigged to be difficult to complete. (A brace of putty was inserted so that more force was needed to open the drawer.) After this initial self-experience, children saw an adult perform a novel act before taking a turn at the task. For example, the adult pressed a button before opening an identical drawer.

For the test phase, children had another chance to complete the task. The critical question was whether children's own prior experience would influence their imitation on this final attempt. In contrast to children who had an easy experience with the task, children who had a hard time were almost twice as likely to take up the adult's example and perform the novel act; Those children who struggled to open the first drawer were more likely to push the button before trying to open the final drawer. A variation on this procedure indicated that preschoolers also take others' efficacy with a task into account when imitating (Williamson and Meltzoff, 2011).

Implications for Parenting and Education

Studying imitation in controlled contexts can provide insights about children's learning processes more generally. Presenting children with an easy problem may encourage them to explore and try different approaches for solving it. In contrast, letting children struggle with a difficult problem may help them realize that they need help. This may make them more likely to take up another's example. An additional finding from these studies is encouraging to me, as a parent and an educator. Children are usually given only minimal instruction during the test period of imitation tasks. For example, they might be told, 'Now it is your turn,' and given the materials. However, in several of these studies children often reproduced more of a model's demonstration when they were explicitly instructed to imitate ('Do what I did'). Thus, a lack of imitation does not necessarily indicate a lack of learning.

Social Considerations

Although considering imitation as a functional process (as a way to acquire new skills and behaviors) is a useful framework, it does not explain all of the variation in children's imitation. As highlighted by Uzgiris (1981), imitation is an inherently social process. Reproducing others' acts is a way for young children with limited language skills to engage in rudimentary social exchanges with peers (Nadel, 2002). Copying others' acts also highlights similarities between individuals. Thus, imitation is also a way to conform or affiliate with others. Indeed, when 5-year-olds were primed to feel excluded from a social group, they showed increased imitation relative to children who did not feel excluded (Over and Carpenter, 2009). Considering the social situation helps to explain when and why children imitate.

Opportunities for imitation are often embedded in a social interaction. If an adult does not verbally engage or make direct eye contact, children are less likely to imitate (Nielsen, 2006; Brugger et al., 2007). Additionally, although infants and young children do imitate novel acts from behaviors they see others perform on TV, live demonstrations are often more effective than are televised ones (e.g., Barr and Hayne, 1999; Hayne et al., 2003; Meltzoff, 1988c; Nielsen et al., 2008). This *video deficit effect* is likely partially explained by difficulties transferring 2D representations to 3D objects (for review, see Barr, 2010). However, studies that manipulate the contingency of the filmed actor indicate that reduced social interaction matters too. When a televised actor reacted to children's behaviors via a closed-loop TV system, 24-month-olds showed improved imitation relative to when they saw the same acts presented by a traditional, passive television display (Nielsen et al., 2008).

Within a social context, children respond to cues provided by the model as to the importance or intentionality of a behavior. For example, when toddlers were shown two acts leading to an outcome, one overtly marked as intentional ('There!') and one marked as accidental ('Woops!'), children were more likely to imitate the one that appeared purposeful (Carpenter et al., 1998). Children's imitation is also influenced by a specific set of pedagogical cues that parents spontaneously employ when teaching their children novel behaviors (Williamson and Brand, 2014). The modifications parents make, called 'motionese,' include closer proximity to the partner, use of a larger range of motion, more repetition, and more gazes to the partner (Brand et al., 2002, 2007). In one experiment, 2-year-olds who saw research assistants demonstrate a series of novel acts on four objects using motionese produced significantly more of the target behaviors than did children who saw an unembellished adult-directed action style (see **Figure 2**).

Figure 2 Motionese influences imitation. (a) Examples of the adult-directed and motionese (infant-directed) action style used in demonstrations to children. (b) Children who saw the embellished infant-directed action imitated more than did children who saw the more subtle adult-directed action, who in turn produced more target acts than children who did not see a demonstration (baseline). From Williamson, R.A., Brand, R.J., 2014. Child-directed action promotes 2-year-olds' imitation. Journal of Experimental Child Psychology 118, 119–126, reprinted with permission.

There are several ways that motionese may enhance children's imitation. For one, the cues used in motionese may help establish what Csibra and Gergely (2006) call a pedagogical context. By this account, humans have evolved to give and respond to cues (such as eye gaze) that indicate what information is new and should be learned. In addition to establishing a pedagogical context, motionese may draw children's attention and may help children identify important parts of acts. It should be noted, however, that this rich pedagogical information is not necessary for children to imitate. In Williamson and Brand's (2014) study, even children who did not see the pedagogical embellishments (those in the adult-directed action group) showed some imitation. Additionally, children can learn new behaviors and when to imitate from observing interactions between other people (Repacholi and Meltzoff, 2007; Herold and Akhtar, 2008; Nielsen et al., 2012b).

The identity of the model also matters for children's imitation. Although several studies indicate that infants and young children are more likely to imitate novel acts demonstrated by an adult versus a child (Seehagen and Herbert, 2011; Wood et al., 2012; Zmyj et al., 2012), when familiar acts are demonstrated, peers are more effective models than are adults (Ryalls et al., 2000; Zmyj et al., 2012). Adults who use the child's own language (Buttelmann et al., 2013) or accent (Wagner et al., 2014) are more likely to be imitated by children than are adults using a nonnative language or accent. These interactions suggest that the identity of the model may lead to different motivations for imitating. On one hand, there are benefits to learning from individuals that are likely to be knowledgeable (e.g., adults). On the other hand, it may also be motivating or easier to imitate someone like you, such as peers or members of your own (versus other) social groups.

Practical Implications

Considering the social context and ramifications of imitation has important implications for considering developmental disorders involving atypical social cognition. In particular, Autism spectrum disorder (ASD) is characterized by social, behavioral, and cognitive problems (Baio, 2012). Children on the autism spectrum are less likely to imitate than are typically developing children (e.g., Charman et al., 1997; Rogers et al., 2003, 2008), and one hypothesis for this difference is that children with ASD are particularly unlikely to reproduce acts that are used to engage or affiliate with others (Hobson and Lee, 1999; Ingersoll, 2008; McDuffie et al., 2007; Rogers et al., 2003). A precise characterization of how the imitation of children with ASD varies from that of typically developing children has the potential to contribute to early screens for this disorder. Further, understanding how imitation contributes to theory of mind (Meltzoff, 2007) will improve our understanding of what abilities and experiences may underlie this disorder.

Conclusions

Humans are born into rich social systems that children must master to become competent, integrated social actors. One powerful tool for accomplishing this daunting task is imitation. Even early in infancy, children have the capacity to quickly learn from behavioral examples and to retain the information over substantial delays. Through imitation, children can take up and reproduce others' body acts as well as specific behaviors used on objects. Children can also infer the underlying goals and strategies directing observed surface behaviors. Thus, with imitation, children are well-equipped to acquire the tools, practices, and customs of their cultures.

Historically, imitation has been an important phenomenon for researchers studying child development. It has been (and continues to be) used as a measure of young children's basic cognitive functions, such as memory and action understanding. It also has been used as an indicator of social understanding and a motivation to interact with others. Within psychology more generally, imitation research is helping identify how human learning differs from that of other animal species. Finally, this area of research has extended to other disciplines, for example, by informing models in neuroscience and promoting educational practices and theory. In the twenty-first century, imitation research continues to grow with theoretical and practical implications for a variety of disciplines across the social and behavioral sciences.

Immigration and Crime in the United States

Richard Stansfield, Rutgers University, Camden, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Immigration has recently taken its place front and center of American politics again, with efforts to achieve comprehensive immigration reform and establish a path to citizenship for undocumented immigrants already in the country. The media discussion generated has focused on how to treat illegal immigrants in the country. Missing from public debate on the topic is an examination of what effect immigration has had on American society. To date, scholars have been in agreement that communities within which immigrants have settled are both safer and economically stronger. In large gateway areas, for example, immigration has been associated with lower crime rates, economic revitalization, and reductions in concentrated poverty. While the increase in Hispanic populations cannot be unequivocally tied to these positive trends, immigration has fundamentally changed the character of urban America. This article will briefly examine the theoretical connections between immigration and crime, before discussing evidence searching for a relationship between these elements, the importance of contexts and potential areas of growth for the immigration-crime literature.

Introduction

The United States witnessed significant and rapid changes in society brought about by immigration from all over the globe. Immigration reached historically high levels during the 1990s, particularly from Central and Southern America, so that now 15% of the population is Latino American. With very visible changes in the social landscape of America, immigration was accompanied by vehement antiimmigrant public sentiment and an introduction of tough bans on illegal immigration in some states. At the heart of public outrage was the belief that recently arrived immigrants, especially undocumented immigrants, represented a substantial criminal threat (Longazel, 2013). This belief tended to be strongest among native-born individuals, especially those with an inflated view of the relative size of the immigrant population. The antiimmigrant public opinion mirrored that witnessed in Western Europe, where the response to growing racial heterogeneity often took repressive and antidemocratic forms, including defining excolonial subjects and new immigrants as threats to the national culture.

Missing from public debates on the topic has been the examination of what effects immigration has had on the communities of their new destinations. The value-laden term 'immigrant' as measured in American studies of immigration and crime has referred to persons born outside of the United States (synonymous with the term 'foreign born'). This immigrant status was typically determined by a question on birthplace in the census questionnaire, and conceptually distinct from whether a person has become a naturalized US citizen. Since the early 1990s, as the immigrant population (especially the undocumented population) increased sharply to historic highs, the rates of violent crimes and property crimes in the United States decreased significantly, in some instances to historic lows. Moreover, data from the census and a wide range of other empirical studies showed that for every ethnic group without exception, incarceration rates among young men were lowest for recent immigrants, even those who were the least educated. Subsequently, the growth of immigration was argued to be one of the key reasons for the crime decline in the United States since the early 1990s. This article will briefly examine the theoretical connections between immigration and crime, before discussing evidence searching for a relationship between these elements, the importance of contexts, and potential areas of growth for the immigration-crime literature.

Theory Connecting Immigration and Crime

Sociological and criminological studies of the immigration and crime relationship are not new. In many ways, today's debates are greatly similar to debates about the arrival of European immigrants to the United States at the turn of the twentieth century. Edwin Sutherland was one notable sociologist of the early twentieth century who saw the utility of using social science to examine the immigrant–criminality link. Sutherland (1947) witnessed that any link between immigration status and crime was in fact a function of the social change going on around immigrants in their new destination cities, wherein immigrant youth faced an increased exposure to conditions of poverty, poor health, and Americanized cultural norms favorable to criminal offending. Sutherland argued that there was not anything inherently criminal about America's newcomers, rather any connection that did exist between immigrant status and crime could be explained by environmental conditions.

This line of thinking was fleshed out by recent scholars of community crime under the label of *social disorganization theory*. Social disorganization refers to the inability of a community structure to realize the common values of its residents and maintain effective social control (Bursik, 1988). That is, social disorganization addresses the structural barriers that impede the development of the formal and informal ties that promote the ability of the community to solve common problems. As the United States underwent significant change in the early twentieth century from small stable farming communities to large industrial cities, Shaw and McKay (1931) hypothesized that inner city Chicago was characterized by residential instability, ethnic heterogeneity, and poverty. Poverty was thought to be criminogenic as it prevented communities from mobilizing formal and informal social control mechanisms.

Residential instability was seen as a barrier to social network development, important for developing and maintaining a system of informal social control. And ethnic heterogeneity, accompanied by fear and mistrust, was thought to impede communication. As the post-1965 wave of Latino immigrants settled in predominantly urban neighborhoods subject to these same community conditions, the theory of social disorganization provided a framework for scholars to suggest that recent immigration would contribute to community crime because of the high population turnover and increasing population heterogeneity that accompany the immigration process (Shihadeh and Barranco, 2013).

The behavior of specific ethnic groups and their incorporation into specific societies have been examined in the context of a number of other sociological and criminological theories too. Some of these assumed that the motivation for crime preceded arrival to the host society. The *importation model*, as Wortley (2009) described it, assumed explicitly that the individuals chose to leave their land of origin to achieve criminal objectives in the destination society. This model has explained the activities of terrorist organizations that have operated within the United Kingdom in the past decade or the operation of Mexican drug cartels within the United States. In an interesting analysis of the viability of the importation model, Varese (2006) examined how northern Italian mafias migrate. Varese's analysis of two deliberate attempts to transplant mafia branches in new territories highlighted that supply on its own was not sufficient. Transplanting a criminal group, in this case, was only successful when combined with the presence of a local demand for criminal protection. Thus while the importation perspective has wide conservative appeal (Wortley, 2009), it is important to consider environmental conditions and opportunities in the new destination.

Higher rates of criminal involvement, for example, may be related to the level of blocked opportunities and other social circumstances. The viability of these perspectives is also dependent on the underlying motivation behind immigration. The motivation for immigration to the United States is complicated and nuanced. Patterns of immigrant settlement varied historically based on industrial shifts, economic needs, and policies of both sending and receiving areas (Durand and Massey, 2004). In general, however, the reason most individuals from Central and Southern America chose to enter the United States, legally or illegally, was because of the gap between life aspirations and the local realities of achieving them, realizing that their country of origin may stay poor for several generations to come (Portes and Rumbaut, 2006). Thus for the most ambitious and the most resourceful, economic opportunities and the sustained demand for immigrant labor by US employers, made immigration to the United States an attractive way to overcome this contradiction. *Economic theories*, therefore, also proved persuasive in predicting an increase in crime in communities with large concentrations of new immigrants. As an example, new arrivals were thought to initially be faced with limited opportunities entering into the labor market due to language barriers, a lack of well-paying jobs within close proximity, and discrimination (Waldinger, 1993). In the face of restricted legitimate opportunities, recently arrived immigrants were expected to turn to economic acquisition crimes, including instrumental violence, to fulfill their aspirations (Lee et al., 2001).

While all of these theories suggested why immigrants themselves may have increased the likelihood of crime, other scholars have turned this question on its head. Instead, some scholars have asked whether the arrival of immigrants spurred a violent or criminal reaction among existing residents in the host society through changing the structure of the local labor market. To the degree that immigration floods the market with unskilled workers it may weaken the labor market positions, and thus increase the criminal propensities, of both immigrant and native workers alike (Wadsworth, 2010). Communities within which recently arrived Hispanic immigrants and low-income Blacks share the same residential neighborhoods have long been marked with conflict over the ability of Hispanics to obtain jobs, and a perception among Blacks that undocumented workers took jobs away from Americans. And employment trends confirmed the emergence of recently arrived Hispanic immigrants in industry sectors traditionally occupied by low-skill African-American employees (Bean and Stevens, 2003). With a reputation as hardworking employees, newly arrived immigrants may have attracted employers, increasing the level of competition over low-wage jobs.

Empirical Evidence

Despite these theoretical grounds, the evidence has been overwhelming that today's immigrant gateways, in the United States at least, saw some of the largest reductions in crime. As Sampson (2008) discussed, crime in Chicago dropped as immigration surged in the late 1990s. And this was not just limited to recently arrived first-generation immigrants. Evidence also suggested that the second generation integrated successfully into Chicago life, even while maintaining much of their ethnic heritage (Kasinitz et al., 2008). Chicago aside, a growing body of empirical research has considered the relationship of recent immigration and violent crime in contemporary American society with remarkably consistent findings that the presence of new Latino immigrants in neighborhoods or cities resulted in either a negligible or a negative effect on criminal violence (Lee et al., 2001; Martinez and Valenzuela, 2006; MacDonald and Sampson, 2012). Ramiro Martinez and Matthew Lee sum this up nicely in a (2000: p. 496) report for the National Institute of Justice: "the major finding of a century of research on immigration and crime is that immigrants … nearly always exhibit lower crime rates than native groups." While many studies continued to support the notion that the mere presence of recently arrived immigrants has not increased violence, recent scholarship has moved beyond this. Martinez and Stowell (2012), for example, considered the different contexts of an emerging majority Latino city in San Antonio and a heavily Cuban-origin city since the 1980s in Miami. While the authors considered different points in time, different types of homicide, and different types of regional concentration, they still found clear results across time and place, and at both the national and local level – that more immigrants did not mean more homicide.

A smaller number of studies assessed the effects of recent immigration on aggregate property crime rates, with more

mixed results. Hagan and Palloni (1998) first suggested that immigrants may be more likely to engage in property, rather than violent offenses, due to the economic motivation underlying immigration. The authors constructed measures of both legal and illegal immigration within 34 Standard Metropolitan Statistical Areas in 5 southwestern states, and found that the size of the immigrant population was positively related to rates of property crime arrests. Since then, however, empirical results of the immigration-property crime relationship have exhibited more parity with the immigration-violence findings. Reid et al. (2005) examined the relationship of recent immigration and crime across 150 metropolitan areas in the United States. After controlling for relevant demographic and economic influences, they found that the foreign-born population did not increase rates of burglary or larceny. Similar results were found in a 2008 Public Policy Institute of California study of 29 California cities. Finally, in an effort to explicitly examine property offending at the neighborhood level, Stansfield et al. (2013) examined the impact of recent immigration on rates of serious property crime across communities in the fast-growing immigrant gateway of Austin, Texas. Negative binomial regression models with corrections for spatial autocorrelation indicated that recent immigration was not associated with an increased rate of burglary, larceny, or motor vehicle theft once important structural predictors of crime were controlled for.

Why the Crime Protection Effect

While the evidence within the American context suggested a crime protective effect of recent immigration on crime, the next question was why. First, it is important to reiterate that the recent waves of immigrants who arrived in America were not an accurate representation of the sending society, rather they were a selective, economically motivated group with higher aspirations. This notion of *selective immigration* suggests lower criminal involvement in itself (Kubrin and Ishizawa, 2012). It follows that Hispanic immigrants to the United States have been more likely to occupy positions in the labor market (albeit at the low end) than other minorities (Martinez and Valenzuela, 2006), providing stability and regulation in the daily routine, as well as economic sustenance.

The lack of a relationship between new immigration and crime could also be a result of the economic revitalization that results from immigration. There is a growing consensus that immigration revitalized and stabilized local communities (Lee et al., 2001; Stansfield, 2013; Stowell, 2007). Revitalization lessened criminal outcomes, not just among the immigrant population, but also among all population groups through business development and the increase in jobs made for native-born Americans in serving the needs of the expanding population. Many of the jobs created that required more responsibility and skill were likely to be filled by native-born workers (Reid et al., 2005). The past decade witnessed a number of examples of the revitalization of stagnant economies. Queens, New York, has witnessed economic rejuvenation driven largely by the success of Black immigrants from the Caribbean. Similar rejuvenation of inner city areas occurred in Los Angeles, Miami, and other Latino immigrant hotspots (Sampson, 2008).

Additionally, the number of Hispanic-owned businesses has grown at rates far exceeding the growth rate for all US businesses over the past two decades. Data from the 2007 US Census Bureau's Survey of Business Owners showed that numbers of Hispanic-owned businesses in the United States increased at more than double the national rate between 2002 and 2007, reaching a total of 2.3 million Hispanic-owned businesses. Almost half of these, about 45.8%, were owned by the people of Mexican origin. Findings of a University of California Los Angeles (UCLA) study commissioned by the Latino Business Chamber of Greater Los Angeles, where Latino-owned businesses make up the largest share of minority-owned businesses, suggested that Latino-owned businesses have been the key to bringing jobs and revenue back into the economy. One recent study by Stansfield (2013) explicitly examined the role of Hispanic-owned businesses in the relationship between immigration and total property and violent crime rates, confirming that cities with higher rates of new immigration were not associated with higher violent crime rates, and had significantly lower property crime rates. Additional analyses examined whether this relationship was mediated by the presence of Hispanic-owned businesses also yielded empirical support.

In addition to economic resources that Hispanic immigrants brought with them, there is also evidence that speaks to the importance of cultural and structural resources that may have protected immigrants against the forces of low incomes, poor educational and occupation opportunities, and discrimination. Although a diverse group, it is believed that Hispanics do share some core cultural values, some of which may act as a buffer against stresses associated with acculturation and limited opportunity in the United States (Gallo et al., 2009). Theories have been developed, for example, that suggest that features of Hispanic culture, including family stability and religiosity, may have enhanced individual resilience in the face of difficult community conditions (Marin and Marin, 1991). Specifically, Marin and Marin utilized the concept of *'familism'* that represents a mentality in which the needs and objectives of the family are placed over the specific needs of the individual. Familism may have provided the social support network with its associated benefits in the context of adverse circumstances (Gallo et al., 2009). Communities with more immigrants, and in turn more intact families and profamily cultural orientations, may therefore have less crime. Findings from a city-level study by Ousey and Kubrin (2009) supported this argument.

While overall these results of immigration seem largely positive, there are two critical caveats. First, cities vary considerably in how favorable their policies are toward immigrants – something that can have important implications for the economic and community benefit of immigration. In some urban areas such as Austin, Texas, the police department collaborated with local banks to encourage immigrants to open bank accounts in an effort to reduce the risk of robberies. Political efforts to accommodate immigrants and encourage integration also provided strong community benefits in the Delmarva Peninsula (Dunn et al., 2005) and St. James, Minnesota (Carr et al., 2012), for example, whereas draconian measures in the form of local ordinances in Hazleton, Pennsylvania, curtailed the integration of new arrivals. These local contexts are important considerations in the successful integration of newcomers. Second, recent evidence suggests that

prior reporting on the benefits of concentrated immigrants has depicted the Latino community too broadly (Shihadeh and Barranco, 2013). This is discussed further below.

New vs Old Destinations

The economic and social decline of nonmetropolitan America has received less public and academic attention than its metro counterpart, as America's trend over the past century has been one of urbanization. But as small towns have lost their populations to the cities and suburbs, a new influx of immigrants, predominantly Hispanic, has gone the other way, accounting for almost half of the nonmetropolitan population growth in the US since 2000. Understanding the complex interplay between immigration, internal migration, and population growth, and understanding the geographic context of immigration are important tasks for studies of immigration and crime. The majority of existing work on immigration and crime has focused on what the Brookings Institute (2011) terms *major continuous gateways*. New York and Chicago were quintessential immigrant destinations, with large and established immigrant populations for the best part of a century. As job markets in these cities have become saturated, however, immigrants have settled in new destinations that had very small or nonexistent Latino populations up until 1990. This included: *emerging gateways* whose foreign-born populations grew faster than the national rate during the last three decades of the twentieth century, and their immigrant population share has exceeded the national average since 1990 (e.g., Phoenix); *preemerging gateways* like Greensboro and Nashville that had smaller immigrant populations than the other twenty-first century gateways but where immigrant growth has been much faster than the national average; and smaller rural communities that suffered from dwindling populations and economic downturns in recent years.

Existing friendship, professional, and employment networks in major continuous gateways have protected newly arriving immigrants from outside discrimination and against engaging in violence (Sampson, 2008). New destinations, however, have not had significant established ethnic populations (e.g., networks of Latino families and businesses preexisting the recent wave of immigration) and as such lack "the social control umbrella of traditional destinations" (Shihadeh and Winters, 2010: p. 631), depriving new immigrants of a significant source of social capital. This difference in community context was considered an important element for successful integration. Neighborhoods in new destinations have differed in other important ways for recently arrived immigrants too. Segregation and housing research highlighted that Latinos were more segregated in new destinations, with neighbors who were more likely to be poor, contributing to the concentration of poverty. As such, immigrants in new destinations have faced tougher economic and social contexts for adaption, integration, and assimilation (Massey, 2008).

Recent studies by Edward Shihadeh and colleagues examined the effect of Latino immigration to new destinations. Shihadeh and Winters (2010) suggested that Latinos were able to offset some of the lack of existing immigrant community by relying on local religious ecology to keep crime low and community strong. Nevertheless, results also suggested that high Latino immigration areas in new destinations were not the safe havens they were in traditional destinations. Instead Latinos were murdered at an exceedingly high rate (Shihadeh and Barranco, 2010). This relationship between immigration and serious violence existed for only the most recent waves of Latino immigrants, however, those who arrived in the US since 1990 (Shihadeh and Barranco, 2013). The recent body of research from Shihadeh and colleagues also suggested that in these new destinations, the theory of social disorganization (discussed earlier) was apt for understanding the relationship between Latino immigration and crime, exacerbated in conditions of economic deprivation. This has led to the more refined conclusion, that while immigration was paradoxically associated with lower crime, this was not the case for the most recent wave of immigration.

Civic Engagement

Work in this literature must also begin to take seriously the differences among the immigrant population in religiosity and civic engagement. The study of civic engagement, voluntarism, and the strength of community organizations has been a staple of political scientists and social science researchers alike. Seminal work of Robert Putnam (2000) illustrated the critical place of these conditions in community stability and individual lives. The influence of Putnam's concept of 'bowling alone' brought light to the importance of a decline in social memberships and levels of interpersonal trust in the United States. This decline was argued to be particularly pronounced among America's minority populations. The low levels of civic engagement were thought to be a reflection of stagnating social cohesion, trust, and interpersonal social networks, which have been causally associated with crime.

The association between civic engagement and crime can be summarized briefly. Within this framework, Lee and Bartowski (2004) defined social capital as the integration within social networks that promotes norms of reciprocity, trust, and an ethic of civic engagement. Therefore at the individual level, participation in networks and community organizations is an important mechanism of social capital that should deter crime. Furthermore, following from prior research on civic engagement (Sanchez-Jankowski, 2002), attitudes toward civic engagement and knowledge of civic engagement may also be important elements to consider in the association with crime. Following this line of inquiry, scholars within the sociological study of religion have examined the mechanisms through which religious-held beliefs and engagement in religious practice promote civic engagement, social capital, and benefits to the community and a deterrent effect on crime, particularly those crimes that are explicitly condemned by their faith (Lee and Bartowski, 2004).

Immigration has certainly influenced the local religious and civic landscape, yet studies of recent immigration and religion and civic engagement have only just begun to emerge. A rich discussion of immigration, religiosity, and civic engagement in the United States can be found in the work of Stepcik et al. (2009), who considered the immigrant population of Miami in particular. As they noted, many if not most of these

immigrants are highly religious, making religion an essential component in understanding the multifaceted influence immigrants are having on American life. Faith is central to many immigrants' lives as it helps sustain ties to the homeland culture as a mechanism for easing the psychological disturbance inherent in the migration process. Religion also profoundly influences the broader civic agenda of their destination towns and cities, acting as a vanguard for direct engagement with civil society, community politics, and participation in nonprofit organizations. And religious congregations can be a source of social support in and of themselves. Shihadeh and Winters (2010) have demonstrated the importance of a proreligious Catholic presence in new Latino settlement areas, which lowered violence against Latinos. The association of civic engagement and crime has both empirical and theoretical grounds in explaining variation in individual- and community-level violence for Hispanic immigrants especially, yet remains an underutilized theoretical framework for studies of immigration and crime.

Victimization

A wealth of research has explored the contradiction between the public and political rhetoric criminalizing immigrants and the reality of immigration and crime. Recently, scholars have turned their attention to the way that the rhetorical relationship between immigration and crime has increased the risk of immigrants becoming victims of crime. Zatz and Smith (2012) argued that the moral panic about immigration and crime, and the resulting antiimmigrant laws, policies, and local ordinances, made immigrants and their neighborhoods less safe. They specifically identified three key areas that make immigrants, especially undocumented immigrants, vulnerable to violence, abuse, and exploitation. First, Zatz and Smith suggested that the policies designed to curtail the flow of immigrants into the country led to immigrants choosing to cross the border in remote areas where the journey is far more treacherous. This counteractive effect of border control policies, leading to increasingly more dangerous border crossings and less willingness to return back across the border at a later point in time, has been well documented in prior research using the Mexican Migration Project (Durand and Massey, 2004). With widespread fear and belief that the government are not doing enough, scholars have also documented a growth in civilian vigilante groups taking up arms along the border, as part of the public border response that stemmed from a belief that Latino immigrants were 'invading' US society (Chavez, 2008).

Zatz and Smith also highlighted the unique vulnerability of day laborers and domestic workers, with victimization ranging from wage theft, not being paid for overtime or double shifts, assaults, and other forms of violence. Capeda et al.'s (2012) study in New Orleans highlighted how violence can erupt along multiple dimensions: with clashes between displaced African-American workers who feel that they are losing jobs to cheaper migrant labor; clashes between Mexican and other Central American immigrant groups who may have experienced violence and theft during their journey through Mexico; and violence by smugglers and traffickers who are transporting the day laborers across the border (see also Zatz and Smith, 2012).

Finally, there is a patterning of violence in the home and communities against women. Domestic violence scholars have increasingly noted how it is important to examine the intersections of not only gender and race, but also citizenship and nationality. This followed a rise in cases of immigrant women in the United States who were victims of domestic violence, and without legal residence. Furthermore, their abusers used their residency status as a bargaining tool, threatening to call immigration services and request deportation if their partner seeks to escape. The Violence Against Women Act (VAWA) and the Victims of Trafficking and Protection Against Violence Act were created for this reason. Ostensibly these laws allowed victims to break free of their abusers without relinquishing residency or legal status rights. Roberta Villalon (2010) demonstrated the importance of how these intersections are relevant for understanding the experiences of battered women with her study of the Organization for Refugees of America (ORA) based in Texas. And the benefit of these laws and addressing the intersections can be seen in her model case study of Angela. After years of abuse and torture from her husband, Angela visited ORA for their legal services. After 8 months, she was granted residency for her and her three kids by the federal government under the VAWA provisions.

Unfortunately, however, her case was not always matched. Women whose husbands were not US citizens were less fortunate, pointing to a hole in the laws that were created for this very reason. Furthermore, through interviews with foundational lawyers and archival analysis – Villalon demonstrated how the foundational priorities of the organization had shifted into ones of expediency and efficiency. Thus with the power workers had to select parameters for successful cases, the organization in many ways perpetuated the problem faced by those with the most disadvantaged and least privileged identities. While some who appear to be good clients can navigate through the system, those with language barriers, emotional, or mental health problems, or even those without a fixed address faced an uphill struggle being successful in getting their case seen to by ORA. Villalon's work helped illuminate not just the importance of examining the intersection of citizenship with race and gender and how these areas create unique experiences in the realm of domestic violence, but she also highlighted how the very organizations and laws designed to tackle the problem, must attend to even more intersections, including language and abusers of non-US citizenship.

In all these forms of victimization, there is greater risk within new destinations. As discussed earlier, where ethnic enclaves and institutional supports have not fully developed, the immigration and crime relationship may take on very different forms. This is also true for victimization, where a lack of institutional support and expertise in the local criminal justice system may make victims more reluctant to report abuse.

Discussion

Subsequently, a number of important works emerged that examined the potentially fascinating implications of immigration

in new destinations including small rural areas and midsize cities in America's south. Carr et al. (2012), for example, looked at immigration in Hazleton, Pennsylvania, and St. James, Minnesota. In this article, they argued that immigration may be critical for saving dwindling populations and the attendant economic decline in rural areas – if handled correctly from a policy standpoint. They contrasted the different approaches in these two locales to accommodating immigrants, and demonstrated the importance of an approach that considers the economic needs of rural America. In Hazleton, scores of people have used draconian measures in the form of local ordinances to curtail the integration of new arrivals, whereas the conscious effort in St. James to encourage integration between native and nonnative communities provided strong community benefits. As America's immigrant population continues to venture into these new locales, local politics, and immigrant incorporation will become critical issues.

While these areas for future research have an American focus, the lessons are nonetheless applicable to the immigration-crime question in other areas of the world. Immigration to areas in Southern Europe has been far more problematic (Melossi et al., 2009). The newness of these destinations, the lack of institutional support, and the intense racialization of newcomers that mirrors the criminalization and racialization of African-Americans, are all likely suspects in explaining the higher rates of crime involving recently arrived immigrants. Public opinion and the lack of welcoming institutional support seem particularly damning in this case. It is therefore worth reiterating the point that in America, the protective effect of immigration on crime especially, in the United States seems limited to the traditional destinations with high levels of integration, institutional support, and opportunity. Difficulties are far more pronounced in newer destinations. Yet the literature seems quite clear in that the explicit policy efforts of these new destinations go a long way in determining the success of integrating new immigrants (Dunn et al., 2005). In large gateway areas and new destinations that have welcomed immigration, immigration has been associated with economic revitalization, reductions in concentrated poverty, and lower crime rates.

Abstract

The growing number of immigrants and its importance in the demographic changes being experienced in the United States have resulted in a surge in immigration research in the last two decades. This article is an effort to tap into the multidisciplinary literature on immigration to bring the issues that are capturing the attention of the most recent scholarship, pointing to data limitations and gaps. We identify family-based immigration, integration, enforcement, documenting the undocumented, the effects of immigration on the wages of native workers, and inequality as the most pressing issues in current immigration research.

Overview of US Immigration

As of the writing of this article, there were 232 million international migrants in the world – 3.2% of the world's population (Migration Policy Institute Data Hub http://www.migrationpolicy.org/programs/data-hub). At 40.8 million foreign-born in 2012, United States has by far the largest number of world immigrants (Migration Policy Institute Data Hub Migration Policy Institute Data Hub http://www.migrationpolicy.org/programs/data-hub). According to Census Bureau's projections, mid-twenty-first century will be the first time that immigration will surpass natural increase as the main driver of US population growth (U.S. Census Bureau Population Projections: http://www.census.gov/population/projections/data/national/2012.html). As shown in **Figure 1**, the percentage foreign-born in the United States has been growing since 1970 standing at 13% in 2012.

The foreign-born population residing in the United States is composed of naturalized citizens, lawful permanent residents, aliens with temporary residence permits, and those residing illegally. The American Community Survey provides information on whether a foreign-born person is a US citizen or not. In the 2012 American Community Survey, 46% of the foreign-born persons not of American parents reported to be naturalized citizens (IPUMS, American Community Survey 2012 https://usa.ipums.org/usa/). The remaining of the foreign-born population are noncitizens. These data do not provide information about immigration status of noncitizens. The Department of Homeland Security (DHS) produces estimates of the number of legal permanent residents and nonimmigrants on temporary visas. The latest estimates show that there were 13.3 million legal permanent residents in the United States and 1.9 in temporary statuses (DHS, Immigration Statistics Publications: http://www.dhs.gov/immigration-statistics-publications).

DHS and The Pew Hispanic Trends Project produce estimates of the unauthorized population. Estimates from DHS for 2011 based on the American Community Survey put the number of unauthorized immigrants at 11.5 million (DHS, Immigration Statistics Publications: http://www.dhs.gov/immigration-statistics-publications). The most recent estimate from Pew for March 2012 was 11.7 million (Pew Research Hispanic Trends Project: http://www.pewhispanic.org).

A distinct characteristic of the US immigration system in comparison to other countries is the preponderance of family ties in visa allocation. Family reunification has long been the foundation of US immigration policy. Between Fiscal Years (FY) 2003 and 2012, United States awarded an average of 1.03 million legal permanent resident visas annually (DHS Immigration Statistics: http://www.dhs.gov/immigration-statistics). About two-thirds of these visas were awarded based on family relationships to US citizens and legal permanent residents (**Figure 2**).

In addition to family reunification, the granting of permanent residence visas is also driven by humanitarian, economic, and diversity reasons. In FY 2012, 154 614 or 15% of all permanent resident visas went to refugees and asylees (noncitizens who have been granted asylum). Another 14% or 139 000 of visas were awarded based on employment and skills. But when counting only the worker, not his or her family, the percent of all visas awarded in the basis of employment and skills was only about 6%.

The United States also awards permanent visas to diversify the country of origin of the immigrant population. A lottery is conducted among intended immigrants from countries with a low number of people admitted to the United States. Diversity visa participants should have at least a high-school

diploma or have, within the past 5 years, a minimum of 2 years of experience working in a profession requiring at least 2 years of training or experience (Migration Policy Center, How the US Immigration System Work http://www.immigrationpolicy.org/just-facts/how-united-states-immigration-system-works-fact-sheet). This group accounted for 4% of all legal permanent visas awarded in FY 2012.

The Merits of Family-Based Immigration

The predominance of family ties in awarding legal permanent visas has generated a debate on whether United States is losing international competitiveness by not putting more emphasis on skills in awarding visas, as other economically developed countries do. Examples of this concern can be found in various bills presented at Congress, which stress putting more attention to skills in awarding legal permanent visas of which the most recent are such as S. 744 and H.R. 2131 (Govtrack.us: https://www.govtrack.us).

Researchers have compared family and employment immigrants and have tried to answer whether class of admission makes a difference in terms of the economic standing and economic progress of immigrants. A further indictment on immigration policy is the fact that researchers have also examined if the labor market quality of immigrants have declined across successive entry cohorts.

Since there is no national data containing information on the class of admission under which an immigrant gained legal permanent residence, most work comparing family and employment immigrants use data from United States Citizenship and Immigration Office on specific cohorts that were granted permanent residence. The immigrant-level data are not public and their use has to be procured through special permit from the DHS. Moreover, information contained in these data is quite limited. It does contain information on class of admission, year visa was granted, and a few other variables such as occupation, age, gender, and marital status, but not earnings. With these data and imputing earnings based on the average earnings of the occupation from other data sources, studies have found that employment-based immigrants have higher earnings than family-based immigrants (Akresh, 2006; Barrett, 1998; Jasso and Rosenzweig, 1995).

Another glimpse into the merits, or lack thereof, of family-based immigration comes from the 1996 New Immigrant Survey Pilot – a pilot study of immigrants who became legal permanent residents in 1996, with retrospective information on occupations (Akresh (2006)). The study reports that family immigrants have a lower occupational index than employment immigrants and experience more downward occupational mobility than employment immigrants.

While it appears that employment immigrants have higher earnings, due to the paucity of longitudinal data on immigrants we do not know if family immigrants become like employment immigrants with time, nor how long this would take. The soon to be released second wave of the 2003 New Immigrant Survey will shed new light on the performance of immigrants by class of admission. This survey is a random sample of immigrants who became legalized in 2003 and were interviewed in that same year and again in 2007. It contains information on a host of social and economic variables as well as their class of admission.

Given the paucity of data on class of admission, the merits of the current immigration policy system is being discussed within the banner of immigrant quality. The large representation of persons with low levels of education in the immigration flow and the shift in sending countries after enactment of the 1965 Immigration Act have prompted discussions on whether recent immigrants are of lower labor-market quality than prior immigrants. This question is not at all new since even economists' writings from the late-1800s bring concerns about declining quality of immigrants (see references in Card, 2009). But the availability of microlevel Census data brings empirical precision to this question.

Researchers have compared the entry earnings of successive cohorts of immigrants, relative to native workers and most have found that the labor market quality of immigrants has declined (Borjas, 1985, 2013; Funkhouser and Trejo, 1998; LaLonde and Topel, 1991). But Jasso et al. (2000) claim that to assess the quality of immigrants and to make assessments about immigration policy we must look at legal immigrants and Census data used in other studies that include unauthorized immigrants. Their data on legal husband immigrants from 1972 to 1995 do not show declines in quality, measured by the average occupational earnings. This finding reveals the importance of differentiating between legal and nonlegal immigrants in immigration research.

As more data points become available through the Census and American Community Survey, it has become evident that there is no permanent feature to the labor market quality of US immigrants. Borjas and Friedberg (2009) find an improvement in quality for the immigrants that entered after 1990 attributing it to the increase in the number of employment immigrants resulting from the 1990 Immigration Act. Changes in quality are also evident in the USCIS microdata on different

cohorts of immigrants who were awarded permanent resident visas (Barrett, 1998; Jasso et al., 2000).

Are Immigrants and Their Children Integrating to the US Economy and Society?

The integration of immigrants into US society and economy has been a long-standing theme in the immigration scholarship. The word integration (the term assimilation is also often used) broadly refers to the extent to which, with time in the United States, immigrants' outcomes resemble those of natives on indicators such as income, employment, occupations, fertility, household structure, English language abilities, and civic engagement. Assimilation in earnings takes place because, with time in the United States, immigrants invest in human capital such as education, learn the English language, and accumulate US labor market experience, and these investments increase earnings (Chiswick, 1978). Alternatively, assimilation can be the product of a learning process or job search. With time in the United States, immigrants learn about the US labor market and this knowledge produces a better matching between jobs and skills and a better pay (Daneshvary et al., 1992). Sociologists refer to Anglo conformity, predicting convergence of immigrants to the outcomes of the middle class (see citations in Valdez, 2006). In 1993 Portes and Zhou introduced the concept of segmented assimilation. According to Portes and Zhou "the question is into what particular sector of American society a particular immigrant group assimilates" (p. 82). These authors offer that immigrants assimilate to different segments of the society in three main pathways: assimilation into the middle class; assimilation into the urban underclass, and the preservation of immigrants' culture and values. This perspective has generated a proliferation of research about what assimilation paths are immigrants following, especially the second generation (Greenman and Xie, 2008; Hirschman, 2001; Rumbaut, 1997; Valdez, 2006).

One integration outcome that has received a lot of attention is earnings. Economists have addressed if the earnings of immigrants converge to those of natives. Due to a lack of longitudinal data, this question has been addressed with synthetic cohorts from Census data. The work of LaLonde and Topel (1992) exemplifies this work, finding that the earnings gaps between immigrants and natives are closed within a period of 10 years in the United States.

A problem with synthetic cohorts is that they cannot address selectivity of emigration. If people who emigrate are those with lower earnings. (Hu, 2000; Lubotsky, 2007; Schwabish, 2011), then assimilation patterns from synthetic cohorts may exaggerate the speed at which immigrants catch up with natives. Recently, researchers have used earnings data from the Social Security Administration to follow immigrants' earnings for a long period of time and a few other studies have matched CPS respondents across interview rotations to follow immigrants' earnings for up to 2 years. These studies paint a more dire picture of earnings assimilation, showing little if any earnings growth across time, at times even declines, and assimilation rates much lower than those from synthetic cohorts (Hu, 2000; Schwabish, 2011; Lubotsky, 2007; Kim, 2013).

Most recently and with the advent of data on youth, research on integration has been expanded by looking at the performance of the children of immigrants and testing theories of segmented assimilation. With Adolescent Health Data, Greenman and Xie (2008) analyze a broad set of outcomes and find that assimilation, measured as years of residence in the United States, generation, ethnic composition of the neighborhood, and ethnicity of friends, have a positive effect on some outcomes and negative in others. Using data from CPS on place of birth of mothers and fathers, Card (2005) finds that the wage and the educational gaps with natives are almost closed by the second generation.

The second generation may be the key yardstick by which to assess immigrant integration (Card, 2005). Data sources on immigrant children and youth such as Children of Immigrants (Rumbaut, 1997), Education Longitudinal Survey, and Adolescent Heath allow for examination of a wide variety of outcomes to test hypotheses about integration of the second generation, opening ample opportunities for future research.

Enforcement and the Well-Being of Immigrant Families

Since the 1990s, the levels of immigration enforcement have increased and the range of enforcement practices have widened with the cooperation between federal and local governments, and with state-of-the-art technology (Meissner et al., 2013). Hagan et al. (2011) describe three laws passed between 1996 and 2000 making it easier to deport an immigrant by increasing the type of deportable offences, weakening judicial review, and reducing the ability of the migrant to appeal: the 1996 Illegal Immigration Reform and Immigrant Responsibility Act (IIRIRA); the Antiterrorism and Effective Death Penalty Act of 1996; and the USA Patriot Act of 2001. Enforcement escalated after 9/11. Between FY 2005 and 2012, 2.8 million persons were removed from the country, almost twice the amount from the previous 8 years (DHS Yearbook of Immigration Statistics: http://www.dhs.gov/yearbook-immigration). Most of the deported are from Mexico and Central America.

In the last few years, researchers have started to put out basic information about deportees and analyzing the consequences of enforcement for immigrant families, particularly children. The report *In the Shadow of the Wall* (http://las.arizona.edu/sites/las.arizona.edu/files/UA_Immigration_Report2013web.pdf), sampled 1113 persons who were deported to Mexico. Deportees were interviewed in ports of entry in Mexico immediately following deportation and in migrant shelters in Mexican cities. This study found that 82% of the deportees were men and their median age was 31 years old; 22% had citizen children and 42% were the sole provider. In a survey of 300 deportees taken in El Salvador, Hagan et al. (2008) also found that most were men, in the ages of 18–30 and that 30% had spouses or children in the United States.

Most studies on the impacts of enforcement on families and children are qualitative and based on small samples but several patterns are evident from these studies. It is clear that there is family separation after deportation and that this affects the income of the family left behind (Capps et al., 2007; Hagan et al., 2011). Children's mental health is also affected

(Capps et al., 2007; Hagan et al., 2011). This research also shows that increased enforcement has injected a fear of deportation among unauthorized immigrants (Hagan et al., 2011; Dreby, 2012). Dreby (2012) articulates that it is not the deportation itself but the possibility of deportation that has affected an even greater number of children, even among children whose parents are not at risk of being deported. Dreby finds that increased enforcement has caused children to conflate immigration with illegality, and Menjivar and Abrego (2012) describes how deportation fears spread even among documented immigrants.

Immigration is a social process (Massey, 2004). Having a migrant parent, a migrant sibling, and a migrant child all separately increase the odds of leaving on a first undocumented trip substantially and significantly (Massey and Riosmena, 2010). But enforcement has had an effect on unauthorized immigration. Several studies using the Mexican Migration Project find that border enforcement reduces undocumented immigration (Angelucci, 2012; Hanson and Spilimbergo, 1996; Lessem, 2012; Thom, 2010). Angelucci (2012) concludes that during the most recent period of high enforcement in her data (1997–2003) enforcement actions were a significant deterrent to in-migration, while the effect on average duration of stay became smaller, leading to a decline in the net flow of undocumented immigrants.

Another aspect of enforcement is happening at the local level. Researchers are starting to sort out the effects of local policies on mobility, access to services, and informal work (Amuedo-Dorantes et al., 2013; Lofstrom et al., 2011).

There is a dearth of research about enforcement and employers. Bringing in the employers perspective can enhance our knowledge about effectiveness and consequences of immigration enforcement.

Documenting the Lives of Undocumented Immigrants

With the rise in undocumented immigration, researchers have recognized the need to document the lives of undocumented immigrants. For a long time, the only information available on unauthorized immigrants was population estimates nationally and for the largest states. But this changed with the Mexican Migration Project (http://mmp.opr.princeton.edu/home-en.aspx). The Mexican Migration Project is possibly the earliest concerted effort to collect data on undocumented immigrants and their households. Data have been collected yearly since 1983, though this is not a nationally representative sample of US undocumented immigrants. The sample is drawn from households in 22 Mexican states.

In the last decade there have been efforts to collect data on undocumented immigrants in the United States, and this has been done primarily through place-based surveys in large immigration cities such as Chicago, New York, and Los Angeles. There is also a good number of ethnographic studies of the undocumented immigrants (Bhimji, 2010, Cleaveland, 2012; Menjivar and Abrego, 2012; Salcido and Adelman, 2004). Most recently, a few studies have surfaced using state-based administrative data such as state wage records in the state of Georgia (Hotchkiss and Quispe-Agnoli, 2013) and records from use of emergency rooms in North Carolina hospitals. (DuBard and Massing, 2007).

These different data sources have documented many aspects of undocumented immigrant lives such as food insecurity (Hadley et al., 2008), domestic violence (Salcido and Adelman, 2004), wages and employment (Hotchkiss and Quispe-Agnoli, 2013; Mehta et al., 2002), type of emergency care service used (DuBard and Massin, 2007), effects of economic trends on migrants lives (Cleaveland), labor rights violations (Bernhardt et al., 2009), the job quality (Enchautegui, 2008), and daily laborers (Bhimji, 2010), among others.

Researchers are also looking at the undocumented children and the citizen children of undocumented parents. Gonzales (2011) brings insights about the experiences of undocumented youth in American schools as they transit from an environment where illegality does not matter to one where illegality becomes central to their lives. Growing up as a child of undocumented parents also has implications for many dimensions of child development (Yoshikawa and Kalil, 2011). An emerging group in the undocumented population and one that will likely generate future research is unaccompanied children, children without lawful immigration status with no parent or legal guardian in the United States. The Office of Refugee Settlement, Program of Unaccompanied Alien Children reported serving an average of 8000 children annually and this figured jumped to 13 000 in FY 2012 and to 25 000 in FY 2013 (https://www.acf.hhs.gov/sites/default/files/orr/unaccompanied_childrens_services_fact_sheet.pdf).

Given the importance of undocumented immigrants in the US population and that immigration status is important in determining eligibility for government programs, the Government Accounting Office (2006) has issued recommendations about how to collect immigration status data on government statistics, but these recommendations have not been adopted by the Current Population Survey, the American Community Survey, nor government health surveys. Currently, two government-sponsored data sets collect information on undocumented status. These are the National Agricultural Workers Survey conducted by Bureau of Labor Statistics and the Survey of Income and Program Participation from the Census Bureau.

Impacts of Immigrants on Native's Wages

The impacts of immigration on the wages of native workers continue to be one of the most researched and most debated topics in immigration. Methodology twists and new evidence keeps bringing new insights to this area of research. Earlier studies estimated the effects of immigrants on native wages through variations in the share of metro-area population that are immigrants; Card (2005) and LaLonde and Topel (1991) exemplify this approach. Most of these studies find small or zero effects of immigration on native wages. But these studies are criticized on the basis that natives in local areas respond to immigration by moving to lower immigration areas (Borjas, 2003). Recent work by Cadena and Kovak (2012) adds a further angle to the limitations of the spatial approach when finding a high mobility rate of Mexican Americans and that this high mobility protects low-skilled natives from negative local-demand shocks such as in the

Great Recession. This research points out to the limitations of the spatial approach in uncovering the effects of immigration on the wages of natives.

More recent studies use a structural approach, departing from a production function. The unit of observation is the relative quantities at the national level of workers by skills, experience, and nativity. With this approach Borjas (2003) and Borjas et al. (2010) find large negative effects of immigration on native wages, especially for workers with no high school graduates-with no further education, but effects on college-educated are also found. Borjas' modeling assumes, and examination of occupations suggests, that immigrants and natives within education–experience combinations are perfect substitutes. Ottaviano and Peri- O&P (2012) using a similar approach find negative but small effects of immigration in the wages of natives. The key difference is that O&P assume that the low-skilled labor is composed of high-school dropouts and high-school graduates and that these two groups are substitutes. Borjas and coauthors, however, assume that the low-skilled group is composed of only high-school dropouts. O&P joining of high-school dropouts and high school graduates-with no further education under the low-skilled group is substantiated by evidence that the substitutability between these two groups is almost infinite (Card, 2009). Therefore, the aggregation of high-school dropouts and high school graduates-with no further education under one skill group is critical in these estimations, reducing the effects of immigration on natives' wages. Although immigration has affected the relative supply of high-school dropouts, it has not affected the relative supply of the combined group of dropouts and high-school diplomas.

It must be noted that this research does not distinguish between documented and undocumented immigrants and we do not know if the lack of competition is due to undocumented immigrants not competing openly in the labor market.

Immigration and Inequality

Immigration has also made its way into current discussions about increased inequality. Immigration could increase inequality directly and indirectly. Directly it would increase inequality if immigrants' wages are more unequal than natives' and if immigrants' average income is different from natives (Blau and Khan, 2012). For instance, a high share of poor immigrants will increase the population at the bottom, while a high share of rich immigrants will increase the population at the top. If immigrants are a small share of the population and their skills are similar to those of natives, effects on income inequality will be small (Blau and Khan, 2012). Indirectly, immigrants could increase inequality if it reduces the wages of low-skilled workers, or if it helps raising the wages of those at the top. A study by Card (2009) concluded that immigration contributed only to a small percent (5%) of the increase in inequality experienced between 1980 and 2000. Blau and Khan (2012) reached similar conclusions showing that immigration increased inequality by 6% among men and by 3% among women.

This literature is quite small now but future research may start looking at the role of second-generation immigrants on inequality, similar to what has happened in integration research.

Immigration, Citizenship, and Integration: Social Work Connections

Ransford Danso, School of Social Work, Ryerson University, Toronto, ON, Canada

Abstract

Immigrants encounter formidable challenges to integration, including exclusionary policies that deny them access to citizenship rights. Deep-level analyses of the unequal relationship between the state and immigrants as well as integration processes and outcomes would enable social workers to develop effective tools to serve the needs of immigrant communities. New social, cultural, economic, political, and legal realities in the post-9/11 era demand that migration studies be given focused attention and moved to a central position within social work. This article introduces an innovative framework to guide social work practice with immigrants.

Introduction

In an increasingly globalizing and diasporic world, migration has transformed the ethnocultural map of nations in profound ways. Countries that decades ago could be described as culturally homogeneous no longer fit that description. Emerging realities indicate that migration will retain its transformative influence in the future, creating new opportunities for social work to engage more meaningfully with migration studies as well as develop tools responsive to the needs of migrant populations.

The corpus of scholarship on globalization and international social work (e.g., Dominelli, 2010) links social work practice to immigrant integration, issues of access, and citizenship (Nash et al., 2006). Social work's connection to immigration goes back to the settlement movement that emerged in nineteenth-century England (Shier et al., 2011). Despite this long history, deep-level analyses of immigrant settlement issues have generally remained a blank spot on the social work scholarly map. This may be due to many social workers' lack of awareness of the challenges immigrants face and the fluid environments in which immigrants navigate their integration today. Lack of training and the feelings of disengagement many social workers experience with immigrant clients exacerbate the problem (Bhuyan et al., 2012). This article offers a synopsis of states' responses to immigration and the role social workers play in policing immigration laws. States' use of neoliberal policies to disenfranchise and exclude immigrant populations is highlighted for the purpose of illustration. I then propose an innovative theoretical framework to guide empowerment social work practice with immigrants.

The State, Immigration, and Social Work

States exploit immigrants' vulnerable position to exclude them from membership by erecting structural hierarchies of belonging and citizenship (Dunn and Jacqueline, 2011). In the post-9/11 era, state laws have led to the gradual erosion of access to social rights for immigrant populations. Even second- and third-generation immigrants, who may be living in the only country they have ever known, are denied rights and entitlements, and remain indefinitely without citizenship (Brubaker, 2010).

In Europe, political and policy discourses deny immigrants access to social and citizenship rights (Davidov and Meuleman, 2012). Restrictive policy measures implemented in Europe over the past decade have led to significant reduction in immigration levels as well as cuts to welfare rights and entitlements for newcomers (Lesińska, 2014). Some Asian countries have instituted exclusionary nation-building programs based on uniform, majoritarian forms of citizenship in defiance of calls to implement inclusive and empowering policies toward immigrant communities (Miller, 2011). Similarly, in Australia, antiforeigner attitudes toward immigrants have led to discrimination in employment and other areas (Nelson et al., 2011). Historically, Australia excluded nonwhites, especially Asians, from entering the country through its White Australia policy (Mann, 2013; Yu, 2014). Before the 1960s, Canada also sought to create a 'white' man's country by preventing the immigration of people it deemed 'undesirable.' Canada implemented a series of policies to stop Chinese people from immigrating to Canada. Beginning with a $50 'head tax' on Chinese immigrants in 1885, the racist practices culminated in the passage of the *Chinese Exclusion Act* in 1923 (Go, 2012).

Social work's relationship with the state on migration is contradictory. Social workers experience ethical dilemmas and value conflicts in which practitioners either obey state laws or violate professional values (Furman et al., 2012). While they fight discriminatory policies and practices, social workers have also been state collaborators. Many injustices are committed against immigrants as a result of social work practices that are sanctioned by government policies on the basis of nation-state boundaries (Moosa-Mitha, 2014). Social workers police state policies in the areas of child protection and welfare services (Martinez-Brawley and Zorita, 2011). Mandatory reporting laws require child protection workers to remove children from families, placing them under state care without due regard for the impact of their actions on families. Immigrant families are often represented in childcare protection in significant numbers in many countries (Putnam-Hornstein et al., 2013).

Social workers also enforce immigration laws regarding undocumented migrants (Furman et al., 2012). State laws require social service providers to report people who may have entered or remained in the country unlawfully. Since

September 2001, America and other Western countries have, under the guise of rooting out international terrorism, instituted stringent national security and immigration laws that oppress immigrant populations (Meissner et al., 2013). Social workers should play a leading role in changing the unequal relationship between the state and immigrants and debunking myths and xenophobic attitudes toward immigrants. They should also ensure that unexamined feelings and biases do not influence their work with immigrants. Practitioners should be knowledgeable about the historical role the state has played in oppressing immigrant communities. Knowledge of the historical antecedents to struggles immigrants face today would equip social workers to develop responsive interventions and influence state policies to better meet the needs of immigrants.

Neoliberalism vis-à-vis Immigrant Integration

Emerging in the 1980s, neoliberalism has become a major driving force behind immigration and social policies in many Western countries (Triadafilopoulos, 2011). Neoliberalism is an approach to social, political, and economic life that discourages publicly funded welfare services (Baines, 2011; Walsh, 2014). Neoliberalism promotes individual skill, self-enterprise, and reliance on the market system to provide individuals with the incomes required to support themselves. People who seek assistance from the government are stigmatized as living off the toil of hardworking citizens.

Many countries have instituted policies that threaten the successful integration of immigrant populations. In Western Europe, state policy on immigrant settlement and integration are increasingly converging in many areas, including the mandatory civic integration courses and tests newcomers must take (Joppke, 2007; Lesińska, 2014). In the Netherlands, prospective immigrants must pass an integration test before they can enter the country, effectively making integration a condition for admission rather than of legal residency and citizenship (Joppke, 2007, 2012). Western European countries have also pursued liberal goals "with illiberal means, making it an instance of repressive liberalism" (Joppke, 2007: p. 1). Canada's neoliberal policies have resulted in welfare retrenchment (Johnstone and Lee, 2014) and the closure of settlement agencies with a long history of serving immigrants (Pashang, 2012) as well as cuts to funding for settlement services that immigrants desperately need to establish themselves.

Exclusion through Disenfranchisement

Voting is a fundamental right and defining principle of both the practice and formal status of citizenship. Citizenship enhances participation and helps immigrants overcome socialization experiences that hinder political engagement (Just and Anderson, 2012). The franchise provides a mechanism for people who are subject to the laws of a state to participate in the creation of those laws (Rodríguez, 2010). Some countries, including Ireland, the Netherlands, and the Scandinavian countries allow noncitizens voting rights irrespective of their nationality. Any citizen of a signatory state of the European Union (EU) can vote in another EU country. New Zealand has one of the most inclusive voting rights for noncitizens; immigrants can vote in local and national elections after 1 year of legal residence (Song, 2009).

The above examples are exceptions as the majority of countries deny immigrants the right to participate in political decision-making processes (Song, 2009). In Canada, state and local laws deny noncitizen immigrants the right to vote (Siemiatycki, 2007), although they may have resided in the country for many years. Immigration policies exploit the economic and human capital of immigrants to give Canada a competitive advantage in the global economy. Similarly, cultural diversity policies showcase Canada as an egalitarian country. Yet, none of these policies actively promotes the political incorporation of immigrants, leading to low levels of political representation particularly for 'immigrants of color.'

The foregoing highlights the need for social workers never to underestimate the power of the state to decide who and how to exclude. The systemic barriers immigrants experience suggest that while globalization and advances in communication technology and transportation infrastructure have rendered national borders more porous, they have not completely incapacitated the modern nation-state. The state has lost much of its past power to control capital (Hanley, 2012) but it has not lost the capacity to regulate the flow of persons across its borders. Membership and access to citizenship have not been recast in a way that bypasses or transcends the nation-state (Brubaker, 2010). Opportunities abound for social workers to fight for inclusive policies and settlement services to facilitate the integration of immigrant populations.

Integration: a Theoretical Overview

The integration of immigrants has become a priority issue on policy and political agendas in many countries. The mix of changing immigration flows, increased ethnoracial and religious diversity, and the politics of national security have intensified debates about social integration, social cohesion, cultural diversity, the collective rights of immigrants, and the state's obligation to protect these rights and promote immigrants' cultures (Banting and Soroka, 2012).

Integration is the process by which immigrants participate fully in the social, economic, cultural, political, and legal fabric of the adopted country. For many immigrants, integration also involves adaptation to new climatic conditions (Phillips, 2010). Integration is a two-way process of engagement, if asymmetrical relationship between newcomers and established residents. Integration fosters a bidirectional flow of views, values, lifestyles, and skills that results in adaptation processes in both settled and immigrant populations (Valtonen, 2008). The newcomers desire to adapt to the new country while the receiving society and its institutions must quickly facilitate the process of making them full citizens with all attendant political and social rights.

Immigrant integration is shaped by four sets of factors: first, the personal characteristics and prior experiences of immigrants; second, the nature and cultural practices of the country of origin; third, the challenges immigrants encounter while in transit; and fourth, the contextual factors within the adopted

country, including state policies and attitudes toward foreigners. For instance, during the twentieth century, the British government developed guidelines on how refugees in Britain should adapt and behave there. They were warned not to appear too 'foreign' and not to congregate together in too conspicuous a way, but conform to a constructed form of Englishness (Manz and Panayi, 2012).

Although shaped by many factors, as integration occurs after migration, contextual factors are likely to exert the most influence on it; the receiving society provides the context within which integration is negotiated. Thus, while integration is considered a mutual process of accommodation between immigrants and the settled population, the 'burden of integration' falls more on the newcomers than on the receiving society. The receiving society exists, a priori, and the newcomers are expected to fit into it. The greatest part of the work of integration is undertaken by the immigrants themselves, although they might be assisted by the adopted country (CCR, 1998).

A Framework of Immigrant Integration

Immigrant integration is often seen as a linear event proceeding from acclimatization through adaptation to incorporation into the new society. Acclimatization is the initial process of immigrants familiarizing themselves with the new society. Immigrants' experiences with culture shock coupled with disorientation vis-à-vis local institutions may indicate the onset of the adaptation phase of integration. Successful negotiation of the acclimatization and adaptation stages ushers immigrants into the integration stage. While the three stages overlap, the speed and degree of integration vary significantly within each stage. For instance, immigrants who integrate economically would be expected to integrate socially and culturally (CCR, 1998).

Danso (2009) has developed a simplified, two-dimensional model (**Figure 1**) to illustrate the complex process of immigrant integration. The model conceptualizes integration as a contested process of conflict and negotiation between immigrants and the receiving society. Political organizing, interrogating dominant-group privileges, struggles over power and acts of resistance are considered types of conflict. Negotiation typically takes the form of advocacy, dialogue, mediation, lobbying, and partnerships. Negotiation is more likely to produce an outcome that is 'positive' while conflict might produce an outcome that is 'negative.' The nature of the conflict or negotiation and the kind of relationship between the immigrants and the receiving society would produce different integration outcomes (Danso, 2009).

To predict a likely integration outcome, the characteristics of the receiving society and the immigrant group are superimposed on each other. The vertical axis in **Figure 1** represents the receiving society and how welcoming or open it is to foreigners, while the horizontal axis represents the migrant community. Both axes range in scale from 'closed' to 'open.' This analysis recognizes the multidimensional nature of integration but concentrates on only two sets of factors: the personal characteristics and prior experiences of the immigrants and the structural characteristics of the receiving society. The model assumes that integration outcomes are largely a function of these two sets of factors.

According to the model, the site of most conflict or negotiation is the intersection of the two axes (point X). Point X is considered the site of 'indeterminacy' or 'uncertainty.' At that point, the receiving society is not sure or does not have clearly defined strategies for facilitating the incorporation of its immigrant populations. At the same point, an

Figure 1 A framework of integration outcomes. Adapted from Danso, R., 2009. Restoring Human Functioning: Impact of Social Policy and Social Networks on the Resettlement and Integration of Refugees in Western Societies. Lambert Academic Publishing, Köln, Germany.

immigrant community is also not sure, at least at the initial stages of settlement, as to how their integration would proceed or what the outcomes would be. While X may constitute a point of no resolution for both groups, it is never a dormant site, but where most action occurs. Any activity at point X reflects a strategy adopted by the receiving society and the immigrant community, which would lead to some predictable integration outcome, and require social work intervention.

Integration Outcomes

Much social science research has focused on the economic and housing experiences of immigrants to the near-neglect of other aspects of immigrant integration. Figure 1 illustrates different outcomes that can result from different permutations of different aspects of the personal characteristics and resources of immigrants and the social structures in the receiving society.

One outcome is labeled 'progressive' or 'double-positive' integration because in responding to their respective concerns, the positive characteristics of the immigrants and the receiving society combine to ensure a healthy compromise that produces proper integration (Danso, 2009). This outcome is based on the assumptions that there are no significant systemic barriers within the receiving society to impede integration; and the personal experiences and characteristics of the immigrants predispose them to integration. Both the receiving society and the immigrants are assumed to be very 'open' such that the positive characteristics of the two groups foster progressive integration.

A second outcome, dubbed 'regressive' or 'double-negative' integration, assumes that the personal characteristics and prior experiences of the immigrants impede integration. Inability to speak the local language, lack of occupational skills, and traumatic life experiences are considered negative characteristics that can drag the integration process. When the negative characteristics and experiences of the immigrants intersect with systemic barriers within the receiving society, these would produce regressive integration outcomes for the immigrant community. In regressive integration, the newcomers and the receiving society are considered 'closed' to each other. According to the model, regressive integration is the polar opposite of progressive integration.

In situations where the immigrants are 'open' and the characteristics of the immigrant community also predispose them to integration, we should expect a 'constricted' integration outcome if the receiving society is 'closed' and less accepting of immigrants. In this case, the immigrants find that systemic barriers within the adopted country frustrate their efforts toward full membership and integration. The degree of constriction would depend on the degree of closure in the receiving society.

An outcome similar to the constricted outcome may be labeled 'rejectionist' integration. This type of integration assumes that the receiving society is 'open' and accepting of immigrants as full members and citizens. Ironically, the offer of welcome and assistance extended by the receiving society is literally rejected by the immigrants. However open the new country is, and however permitting the conditions in the country are, the 'negative' characteristics and experiences of the immigrants hamper their integration. This typically occurs when the immigrants, especially refugees, have experienced excruciating acts of violence resulting in posttraumatic stress disorder for the immigrants. Strong attachment to the past could also prevent newcomers from identifying fully with the adopted country.

As in the case of constricted integration, the degree of rejection would depend on which of the two sets of characteristics exerts the most negative influence as well as the strength of that influence. However, since the receiving society has more powers than the immigrant community, we would expect the structural barriers within the receiving society to outweigh the negative circumstances of the immigrants when there is constricted or regressive integration.

Figure 1 suggests that any outcome that departs from the progressive option necessarily constitutes 'dysfunctional integration' for immigrants. It is so labeled because there is always a negative dimension to dysfunctional integration, regardless of the socio-political, historical, or geographical context within which it occurs. Dysfunctional integration is a product of the wider processes of social exclusion, ethnocentrism, and racialized relations and is typically indexed by spatial segregation, poor labor market participation, disenfranchisement, and denial of social rights for immigrant groups. Dysfunctional integration necessitates social work intervention.

Practice Implications

The model presented above has great potential for social work practice; it positions migration and settlement as sites for social work intervention. The model can facilitate the development of theoretical ideas and practice tools for training cross-cultural and social justice-oriented social workers. It can help social workers to identify areas for advocacy, research and policy development with respect to issues such as civic engagement and access to employment and settlement services. Efficacious application of the model requires social workers to demonstrate the ability to capture the essence of complex social processes involved in immigrant integration. Critical assessment of the issues underlying integration processes would equip practitioners better to understand the nature of the relationship between the receiving society and immigrant communities. Practitioners would then be able to explain how particular integration outcomes emerge from particular social relations between the state and specific immigrant populations. The model also has the potential to inform immigration policy decision making and the design and delivery of culturally responsive settlement services.

'Idiosyncratic Consciousness' and Empowerment Social Work

I introduce the term *idiosyncratic consciousness* to denote social workers' ability to demonstrate deep awareness, acceptance and effective engagement with the 'idiosyncratic self' of the client. Idiosyncratic identities emerge from a person's cultural upbringing, the mannerisms, ways of doing things, modes of

behavior and social interaction that are unique to an individual. Idiosyncrasies are integral aspects of the self; therefore, it is contrary to the goals of empowerment social work to expect people to divest themselves of these important elements of their identity and conform to the norms and expectations of the dominant culture.

Personal idiosyncrasies can hinder the development of a good helping relationship with clients (Heydt and Sherma, 2005). However, the idiosyncratically perceptive social worker embraces them as strengths, rather than as deficiencies, to empower clients. The worker creatively and skillfully uses them to determine the most appropriate intervention approaches to pursue with the client (Diller, 2011; Sisneros et al., 2008). The inability to accept an individual's idiosyncratic self, defined here as idiosyncratic ineptitude, often leads to prejudicial attitudes and ethnocentric behaviors, producing negative client outcomes in the helping relationship.

Applied to migration and settlement, idiosyncratic consciousness requires social workers to be skillful at developing deep understanding of the integration strategies immigrants pursue to bridge the gap between their heritage cultures and dominant social culture. Immigrants engage with two contemporaneous processes: 'acculturation' and 'deculturation' (**Figure 2**), as they negotiate the entanglements of their integration. As immigrants acculturate – by adapting to the receiving culture – they also 'deculturate'; they discard those aspects of their heritage culture that could trigger a cultural tug-of-war with the receiving culture. Such conceptualization broadens the definition of idiosyncratic consciousness to encompass social workers' ability to critically assess how immigrants handle the challenges of their integration in maintaining a balance between acculturation and deculturation. Immigrants develop 'amalgamated identities,' which are the new identities formed as negotiated outcomes between the twin processes of acculturation and deculturation (see Cheng, 2014; Geleta, 2014).

Idiosyncratic consciousness also requires social workers to demonstrate cultural humility and the capacity to integrate diversity principles in practice. Cultural humility describes an interpersonal stance, in which a social worker maintains an other-oriented, rather than a self-focused, ethnocentric perspective that involves respect and lack of superiority toward an individual's cultural background, personal idiosyncrasies and life experiences (Hook et al., 2013; Isaacson, 2014). Cross-cultural humility, competencies, and skills (Diller, 2011; Sisneros et al., 2008) would enable idiosyncratically conscious practitioners to avoid the pitfalls associated with the expectation that immigrants' identities should be supplanted by or absorbed into those of the dominant group. They could also help to liberate social workers from expectations of cultural expertise about immigrants, and to actively engage immigrant communities, inclusive of their cultural differences, in integration and service delivery processes (Ortega and Faller, 2011). Idiosyncratically conscious practitioners eschew ethnocentric inclinations and instead identify ways for responding appropriately to the personal and 'cultural idiosyncrasies' of immigrants. Idiosyncratic consciousness thus extends the notion of cultural competence to include critical analyses of the processes by which immigrants forge new identities as they integrate into the adopted society.

Idiosyncratic consciousness is linked to empowerment social work practice. The empowerment 'paradigm' emerged to counter radical social work's arguments about therapeutic approaches being the only concern of social work practice (Bransford, 2011; Dominelli, 1997). Empowerment social work is emancipatory and transformative in that it strives to change social structures and relations that oppress people (Healy, 2005). It enables oppressed groups to engage with policy decision-making practices and take control of their own lives. Policies are usually developed by people whose lives are least likely to be impacted by the policies; policies are made to serve the interests and needs of the dominant group and to maintain its power (Mullaly, 2007).

Besides requiring practitioners to fight for egalitarian social relations, empowerment social work also requires that practitioners keep abreast with current developments in immigration

Figure 2 'Amalgamated identity' formation.

regulations so they can create responsive interventions with clients to address challenges presented by policy changes. Empowerment social workers partner with clients and social justice-oriented elements within dominant groups (Gibson, 2010; Sisneros et al., 2008) to change unjust policies and interrogate the unequal power relations that deny immigrants access to resources and opportunities.

Transformative social workers can play four key roles in the struggle for social change. Practitioners can be 'initiators' by starting a change process. Initiators do not wait to be encouraged to act; they start a change process whenever necessary. While they recognize the strength in numbers, transformative social workers do not always seek unanimous decisions on issues affecting people's lives. For transformative social workers, consensus is a necessary but not always a sufficient condition for initiating change (Chappell, 2010; Ezell, 2001). Historically, many social change processes were sparked by individuals with a vision to make a difference in society.

Another role for transformative social workers is that of a 'social catalyst.' A worker acting as a catalyst precipitates an action while also undergoing change, for instance, through constant self-reflection. Social transformation is a life-impacting process; therefore, as social workers attempt to create change they must expect to be changed by the very change they want to create. Otherwise, they perpetuate the oppressive status quo they seek to dismantle.

Transformative social workers could also function as 'sustainers' by ensuring that the change process is carried to successful conclusion. As sustainers, practitioners monitor the change efforts to ensure desired goals are achieved and necessary changes implemented as the process unfolds. Social workers can also be 'evaluators' by assessing whether the change process achieved the goal that triggered the process. Evaluation provides practitioners with an overall picture of the change effort as well as opportunities to develop more effective change strategies and plans for future projects.

Conclusion

Few processes transform human society in more profound ways than migration. Arguably, migration will continue as a powerful dynamic in national development, global social change and international relations. Post-9/11 developments at all geographical scales are recasting the state's responses to migration and integration through policy practices that impact negatively upon access to citizenship and inclusion. These developments demand that social work jettison its tenuous relationship with migration and settlement and move migration studies to a central position within the discipline. The emerging realities present challenges that require critical analyses to produce effective tools for addressing the challenges facing immigrant populations. At the same time, they open up vast frontiers of opportunities for social work to make distinctive, path-breaking contributions to migration scholarship. This article argues for the recognition of migration, citizenship, and integration as important sites for social work intervention.

Abstract

The global expansion of capitalism and the concurrent rise of an international system of nation-states are the backdrop against which this article defines emigration, immigration, and citizenship. The article identifies the major features of modern mass migration, outlines an analytic approach to avoid the pitfalls of nationally based biases in studying immigration, emigration, and citizenship, and presents a case study to illustrate the benefits of this approach.

Migration

Migration refers to the movement of people from one place to another, for a time and a distance long enough to significantly disrupt links to the original point of departure. It is the fundamental process underlying immigration and emigration. Citizenship or political membership becomes salient when people cross borders and hence is often examined in discussions of immigration and emigration. A consideration of migration, especially over the last two centuries, is, therefore, a necessary backdrop to defining immigration, emigration, and citizenship.

The process of migration has been driven by the search for daily sustenance and reproductive partners since *homo sapiens* spread from Africa throughout the Eastern Hemisphere beginning about 60 000 years ago (Manning, 2005). By modern standards, these early migrations consisted of small movements that happened over long periods of time. Notwithstanding differences of size and rate, migrations then and in more recent years continue to have in common the drive to find resources. The advent of modern capitalism, however, has driven and transformed migration into the mass phenomenon with which we are familiar today. Mass migration, in turn, has changed social organization, economic exchange, culture, and politics in sending and receiving contexts.

Mass Migrations

Geographic mobility has been a fundamental human activity, but large demographic movements are a relatively modern development. The scope of migrations that started in the fifteenth century was unprecedented in world history. Columbus' voyage marked the beginning of modern, large-scale migration. In the first three centuries, after he sailed from Europe, about two million Europeans crossed the Atlantic and settled in the Americas (Manning, 2005) as part of processes of colonization and the search for better economic prospects. In the same period, traffickers brought eight million Africans, mostly as slaves, to the Western Hemisphere.

Driven by the expansion of capitalism, massive movements of people accelerated dramatically between the 1850s and 1950s, and were comprised of three main circuits. First, about 58 million Europeans and 2.5 million Asians and Africans migrated to the Americas. Second, about 52 million migrants moved from India and southern China to Southeast Asia, the Indian Ocean Rim, and the South Pacific. Another four million moved from Africa, Europe, Northeastern Asia, and the Middle East to Southeast Asia, the Indian Ocean Rim, and the South Pacific. Finally, somewhere between 46 and 51 million people migrated from Northeastern Asia and Russia to Manchuria, Siberia, central Asia, and Japan (McKeown, 2004).

Since World War II, global migration has increased steadily as a result of several factors: population growth (an almost threefold increase in the 60 years preceding 2009), relaxed migration controls between the 1960s and 1990s in major destination countries, refugee flows, and the expansion of the global economy (Moya and McKeown, 2011; see also Castles et al., 2014 for an overview). Absolute numbers of contemporary migrants are from double to triple, what they were in the 1910s and late 1920s. Migration *rates*, however, have been roughly similar to those of the previous 'age of migration.' Compared to migrations before World War II, postwar migrations have been more regulated, women have become nearly half of all international migrants, and the sources of migration have changed. Post-World War II migration has been more global in origin, as only the major destinations were not sending significant numbers of emigrants to other regions.

Global Revolutions

Four global transformations joined to produce mass migration through the 1940s (Moya, 1998). The *demographic 'revolution'* resulted in population growth in Europe, despite the departure of many of that continent's natives. In the economic domain, the combined effect of the *agricultural and industrial revolutions* created surplus labor in some regions and demand for workers in others. As McKeown (2004: 155) notes, "the rice fields and rubber plantations of Southeast Asia were as much a part of the industrial processes transforming the world as the factories of Manchester and the wheat fields of North America."

A *political revolution* resulted in the consolidation of an international system of nation-states, which interacted with a widespread acceptance of the freedom to emigrate to produce legal and organizational structures that, however, variable in the capacity to actually control people flows, affirmed universally accepted ideas and practices with long-lasting consequences. The idea that nation-states should have sovereignty over their borders and be able to select who entered the national territory or its community, for instance, became a fundamental political tenet by the nineteenth century. This

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86150-4

notion had been preceded, however, by the 'exit revolution,' which reflected a consensus on the part of states that emigration could serve their interests and hence should not be restricted as it had into the early nineteenth century (Zolberg, 2007). Allowing exit had become a useful tool to relieve domestic pressures, first as a form of benign neglect and later a liberal policy toward population movement. Those who could vote with their feet, local officials who felt firsthand the pressures of demographic growth and labor demands, and free-market liberal politicians and economists, all supported the exit revolution. In 1922, the International Labor Organization noted in its reaction against post-World War I restrictions on migration from Europe to the Americas that "during the whole of the nineteenth century … [a]lmost all countries kept an open door both for emigrants and immigrants" (1922: 13). The truth was more complicated, since major receiving countries in the Americas and in English-speaking settler states selected immigrants by origin, and sending states like Japan and China sought to avoid humiliation on the global stage by acquiescing to the pressures of receiving states to control emigration (FitzGerald and Cook-Martín, 2014).

Finally, a revolution in transportation technologies changed the scope and reach of migration. The advent of steamships and trains that could transport the inputs of emerging industrial capitalism – coal, iron, timber, cotton, wheat – and workers to harvest, collect, or move these commodities, spurred larger movements of people over longer distances than ever before. Refrigeration technologies in tandem with new modes of transportation could, for instance, make possible the delivery of perishable commodities from the Southern Cone to markets in the major industrializing cities of England. The rise of transportation as an industry with its own political interests also drove mass migration and illustrates the interconnection among the global transformations described (Feys et al., 2013).

These four revolutions were, in fact, entwined and mutually reinforcing. Population growth put pressure on local resources often because of institutional property arrangements. Local authorities had to contend with a growing number of residents unsure of how to make a living under new circumstances compounded by the impact of capitalist modes of production. Authorities relaxed constraints on emigration and pressed national authorities to reflect this approach in policy. A political culture of free movement ensued. Shipping companies, for example, in Hamburg and Bremen, viewed emigrant flows as an important source of revenue, and in turn became political actors in their own right.

Features of Modern Mass Migrations

An important concomitant of these revolutions has been the rise of cities as hubs of domestic and international migrations. Migration has been part and parcel of *urbanization*. Three percent of the world's population lived in cities in 1800, but this proportion rose to 14% by 1900, 30% by 1950, and over 50% at the time of writing (Moya and McKeown, 2011). Cities have been the launching sites and ports of arrival for mass migration over the last two centuries; even if countries are the typical unit of analysis.

Migrations since the mid-nineteenth century have primarily been free rather than coerced, as they had been in the case of the chattel slavery system that predominated beginning in the late seventeenth century (Castles et al., 2014) or the trade in Chinese indentured laborers that emerged in the wake of abolition (Meagher, 2008). 'Freedom,' however, has consisted of (1) severing historical ties to local communities and a commons such that people were free, in the Marxian sense, to move elsewhere in search of other means of livelihood and (2) an ideological accomplishment of capitalism that fashioned subjects as workers who transacted the sale of their labor with employers through contracts entered on putatively equal footing. From prospective migrants' point of view, freedom consisted of having opportunities to find work.

Migrations have been not only among countries, but also *domestic*. Rural to urban migrations within national borders often preceded large migrations from Europe to the Americas, although migrants also moved directly from rural areas in their countries of origin to urban areas in destination countries. Migration has also happened within major migration receiving countries. For instance, after emancipation but during the height of Jim Crow segregation, a movement of blacks began from the south to the rest of the United States. All told, this involved a net migration of over six million people by 1970 (Tolnay, 2003). This particular movement demonstrates the limits of the political ideology of free movement – since white southerners waged a daily struggle to prevent the defection of black workers in search of the 'warmth of other suns' (Wilkerson, 2011) – but also similarities among domestic and international migration. And while these movements were partly motivated by a comparison of labor prospects in the south and elsewhere, the extreme castelike system of the Jim Crow south undoubtedly moved blacks to vote with their feet. Another example of domestic migration is the movement of the U.S. mid-Westerners from the 'Dust Bowl' to California in the 1930s and 1940s, famously depicted in John Steinbeck's novel *The Grapes of Wrath*.

Circularity is another feature of modern mass migration. Seasonal differences, for instance, allowed Italian migrants to work in harvests in the Northern (Europe) and Southern Hemispheres (the Southern Cone) on a cyclical basis. The intentions of even these 'sparrow' workers changed and they settled in Argentina and Brazil. The cycle migration to a new destination, return to a sending country, and remigration to a new destination can also be stretched out over years in the life cycle of an individual or family, or even across generations (Bhachu, 1985). The tightening of border controls since the 1990s and especially since 2001, however, has significantly impacted seasonal and circular flows.

Migration movements have also been deeply *gendered* (Calavita, 2006; Cook-Martín, 2006). To the extent that migration decisions have been made at the household rather than the individual level, as suggested by 'new economics of migration' theories (Massey et al., 1993), they have reflected heteronormative and patriarchal ideas and strategies. In pre-1945 migration, immigration policies gave these ideas the force of law often defining the category 'immigrant' as a male head of household. Emigration policies put different constraints on the departure of young men (e.g., completion of military service obligations) and women (e.g., through morality protection laws that forced them to be accompanied by a male head of household). The postwar feminization of

migration has been linked by scholars to neoliberal market reforms, the massive movement of women into the workplace in the Global north, and implicitly, men's unwillingness to contribute labor in the household economy (Salazar Parreñas, 2005). More recently, legally inscribed conventional gender categories and sexualities have been challenged by the migration of same-sex partners and of individuals who defy traditional expressions of sexuality (Luibhéid, 2008).

Immigration, Emigration, and Citizenship

The preceding overview of migration is a necessary precursor to defining immigration, emigration, and citizenship. If not for the global revolutions described earlier – especially the consolidation of an international system of nation-states as an organizational reality as well as an idea – immigration, emigration, and citizenship would not resonate as they do with scholars and the public at large. *Immigration* refers to entering and settling in a national territory, whatever the intention of people engaging in this process. *Emigration* refers to departure from a national territory to a specific destination.

These terms are not merely descriptive of the direction of movements across national territories, but have a strong moral valence. From the perspective of historical destination countries, immigration has been a primary means of nation making and, therefore, a process to be carefully regulated since it affects the character and prospects of the putative imagined community (Anderson, 1991). The assumption on the part of officials in receiving countries is that desirable immigrants will want to stay and that their settlement is permanent. From the perspective of sending countries, emigration has challenged nationalist assumptions that citizenry and territory should match closely. A response has often been to construct notions of the nation that transcend national borders like the Greater Italy (Choate, 2008) or a Salvadoran or Mexican nation of emigrants (Bibler Coutin, 2007; FitzGerald, 2009). The assumption on the part of state agents in the sending country is that their citizens are abroad for a time and that they will return.

Citizenship refers to the legal link between a state organization and an individual – which entails rights and obligations – and the affective tie between individuals and a nation (Cook-Martín, 2013). Migration has challenged normative ideas of citizenship that see it as a permanent and enduring link. In the contemporary world, citizenship may have more than one state and national referent.

Immigration, emigration, and citizenship, however, issue from the foundational assumption of a world organized into discrete states whose territories and people, more or less match. The assumption is so strong that even self-aware analysts have trouble escaping what Gerard Noiriel (1991) has called the 'tyranny of the national' or the tendency to view migration from the vantage point of a particular state.

A transnational political field approach offers a corrective to nation-based assumptions that shape scholarship on migration. A 'political field' refers to a social space in which individual and collective actors compete over valued symbolic or material resources, such as an imagined nation, workers, or potential citizens (cf Bourdieu, 1991). 'Transnational' refers to an analytic global view rather than one privileging the perspective of a single player in the field. Political fields change over time as organizations develop and institutionalize competitive strategies and hence it is also critical to take a long view. A transnational approach is a useful heuristic device to define and understand the concepts of immigration, emigration, and citizenship. This interpretive framework yields three key insights.

First, terms like immigration and emigration that refer to the direction of migration flows often hide nationalist assumptions. One country's immigration is another's emigration. Moreover, today's immigration may be the source of tomorrow's emigration, depending on changes in economic and network factors causing and/or sustaining migration, as well as on the social, political, and institutional ties that bind people at each end of a particular flow. For instance, the legal and organizational frameworks developed by governments to manage migration at one moment in time can facilitate or hinder future migration often in unanticipated ways. When Italian policy makers at the turn of the twentieth century fashioned nationality laws that extended citizenship over several generations, they created a framework that allowed the descendants of Italians in the Americas to 'reclaim' Italian citizenship after several decades (Cook-Martín, 2013).

Second, analysts are more like to assume that assimilation should be the desired outcome for immigrants if they adopt the standpoint of a particular country rather than a global perspective. The flip side of this problematic view is when sending countries assume that the ties that bind them to 'their' citizens abroad are unchanging and enduring, sometimes over several generations. In the first instance, policy makers, the public, and some scholars view assimilation – or in the European version, integration – as a mostly straightforward and unidirectional process that is inevitable given enough time and facilitating conditions in the receiving context. A healthy debate in the literature on assimilation suggests outcomes are to be empirically explored rather than assumed (Alba and Nee, 2003; Alba, 2005; Brubaker, 2001). The assumptions of sending states with respect to the ties that bind emigrants and their descendants have been explored, but not as systematically.

Finally, the dynamics revealed by a transnational political field approach and illustrated by the examples cited suggest that links among people at two ends of a migration flow cannot be presumed to transcend a particular nation nor can identifications be assumed to endure over time. These phenomena require empirical verification, especially of the causal relationship between formal laws and a sense of belonging. Scholars continue to explore whether laws recognize and consolidate existing affective identifications or whether identifications drive adherence to naturalization and citizenship acquisition (e.g., Bloemraad, 2006; Cook-Martín, 2013).

Migration and Selectivity

A transnational political field approach recommends awareness of the politics surrounding terms like immigration, emigration, and citizenship. A case study of how immigration and nationality laws have been instruments to select 'good' workers and citizens illustrates the promise of this analytical approach. In the Americas, for most of the last 200 years,

desirable workers and citizens have been selected by ethnicity. Racist laws have been more common among countries with greater political inclusion, whether democratic or populist (FitzGerald and Cook-Martín, 2014). Taking a long view of economic and ideological factors on a domestic plane – comprising interest group struggles within a country – as these intersect with those on an international plane – including struggles between and across countries – it becomes clear that there is no iron law linking ethnically selective laws to ideologies like liberal democracy and racism, or to domestic struggles among labor and capital.

On the ideological front, conventional wisdom has maintained that racism has no place in liberal thought and institutions (de Tocqueville, 1994; Higham, 1994; Freeman, 1995; Joppke, 2005). Historical instances of racism in law and policy have been characterized as aberrations to be worked out of the democratic body politic or vestiges of earlier, more primitive social arrangements like slavery (Fukuyama, 1989).

While the received wisdom may sound appealing to those who are philosophically sympathetic to the tenets of liberal democracy, it is empirically wrong and fails to explain the emergence and decline of racist immigration laws. The United States, the main global exemplar of liberal democracy, took the lead in excluding blacks and Asians beginning with its nationality laws in 1790 and immigration laws in 1803.The U.S. laws limited naturalization to whites and banned Chinese immigration *because* it was a democracy. Policy makers in the United States, most notably U.S. President Theodore Roosevelt, argued that whiteness indicated capacity for self-government.

Moreover, undemocratic regimes in Cuba, Argentina, Chile, Uruguay, Paraguay, and Mexico reversed discriminatory immigration and nationality laws and pioneered the explicit deracialization of immigration policies beginning in the late 1930s, a generation or more before Canada, the United States, Australia, and New Zealand. Racial equality has not been inherent to liberalism and is especially fragile in democratic and populist political systems.

Critical race theorists reject the premise of a liberal democracy whose practices have not caught up to its ideals. On this view, much more consistent with historical realities of the last centuries, racism and liberalism have been mutually constitutive, fully compatible, and clearly conjoined in practice (e.g., Mills, 1997, 2000). Yet this view cannot explain the decline of ethnically selective laws and the massive ethnic transformations of countries like the United States and Canada that were historically among the most racially selective. It also misconstrues the factors that lead to the decline of racially selective laws around the time of World War II.

Liberalism was not inherently racist, but neither was it inherently antiracist. Historically its immigration and nationality laws have had a color, and it has been white. Liberalism and racism were not simply two independent and cooccurring traditions (cf Rogers Smith); they were intimately linked. The rising aspirations and decolonization of peripheral countries during the geopolitical conflicts of World War II and the Cold War eventually forced powerful white countries to forego racial discrimination in law; the dismantling of the racist regimes was not an attempt by countries with racist laws to reflect liberal democratic principles or primarily a domestic movement for equality.

On the economic front, a transnational and historically comparative view shows that class conflict has been an important but insufficient explanation for patterns of ethnic selectivity, that exclusively class-based accounts have difficulty explaining the malleability of class preferences in the same countries over time, and that there are numerous instances of economic groups supporting overly racist laws even in the absence of an economic incentive and sometimes against economic self-interest.

The pattern of racial selectivity described in the previous paragraphs becomes evident only by adopting a systemic view that captures relations in an international domain, puts domestic migration politics in that geopolitical context, and examines legal-institutional developments over the long run. A transnational political field approach that is historically relational addresses the serious methodological problem of focusing primarily on Western liberal democracies in the second half of the twentieth century, which yields a skewed picture of which countries modeled the move away from ethnic selectivity. This approach allows analysts to understand how the politics of today shape immigration and nationality policy, how the policies of yesteryear 'tick' within the policies of today, and how policies in one country are shaped by the policies of another. From this perspective, immigration and emigration policies are interactive. Indeed, countries of emigration have played an underappreciated role in shaping the policies of immigration countries (FitzGerald and Cook-Martín, 2014: 27).

Citizenship in an Interconnected World

Concerning citizenship, a systemic approach allows us to see that even nationality law, widely conceived as the domain most subject to sovereignty concerns, is shaped in an international political field that unfolds over time. Chinese were first banned from entry to the United States in the 1880s, and then from naturalization; but during World War II, when the Allies needed Chinese support, the naturalization ban was lifted. Citizenship laws in major emigration countries like Italy and Spain were instruments to counter the 'assimilatory' laws of receiving countries like Argentina, Brazil, and the United States (Cook-Martín and Viladrich, 2009).

Moreover, past configurations of migration and nationality laws can have important consequences in the present. The *jus sanguinis* nationality laws of sending countries offer a means by which the descendants of past emigrants can make claims on ancestral homeland states. Generations after the last Italians arrived in New York, Buenos Aires, Caracas, or Melbourne, their descendants can make claims to Italian citizenship. The descendants of Japanese migrants to Brazil and Peru have had access to a privileged immigration status in Japan, thanks to ethnic affinity policies (Tsuda, 2009). Indeed, the combined effect of *jus solis* and *sanguinis* policies have generated a large population eligible for a second nationality, and a potential revolution in perceptions about multiple nationalities. Over 2.5 billion people live in countries that *de facto* allow for multiple legal citizenships, a number that has grown fivefold since 1960 (Sejersen, 2008). In other words, the writing of laws by states in reaction to the movement of people has resulted in the possibility of multiple affiliations.

Countries vary significantly, of course, in the degree to which they have institutionalized control over migration as well as in their capacity to regulate flows and establish legal membership. Sadiq (2009) has shown convincingly that migrants from neighboring countries in India have made claims to legal citizenship through fraudulent use of authentic documents or through counterfeit papers. Historically, migrants in other latitudes also made claims to a status as immigrants or as citizens through similarly fraudulent means. Traffic in official documents has in fact been at the heart of a 'paper industry' to such an extent that it has caused some to observe the fetishism of papers (Hernández-León, 2013; Suárez-Navaz, 2004).

Conclusions and Implications

Immigration, emigration, and citizenship are contested, political terms that encompass far more than the direction of migratory flows or legal links between a state and an individual. A transnational political field perspective uncovers the complexity and political weight of the terms. 'Immigration' and 'emigration' subsume normative assumptions about the desirability of migrants as workers and citizens, about expected relationships and allegiances with sending and receiving communities, and about the longevity of links between states and migrants.

Moreover a transnational analytic approach has implications for explanations of migration. Scholars of migration explain the movement as the result of 'cumulative causation' by primarily economic and social network factors at points of migrant departure and destination (Massey et al., 1993). Structural- and individual-level economic factors have indeed been central to the movement of people across regions, borders, and oceans. Individuals, families, and their broader networks move in search of better economic options and as a means to diversify risk in an unpredictable capitalist system. There is more to the story, however, than the 'standard economic calculus narrative' (Hollifield and Wilson, 2011; Massey, 1999). The advent of national–territorial state organizations that fence in markets and workers is the very historical innovation that makes human mobility a subject of study. The development of a full-blown international system of sovereign states has made migration a key concern of states that feel such movements challenge their dominion (Zolberg, 1999). The very terms immigration and emigration reflect the interest of state organizations in exercising control over who comes and goes. Demography, law, and the social sciences developed in the context of state organizations and with national interests in mind.

While economic interests have been paramount, the impact of who comes and goes on the perceived community or communities associated with a state (nation or nations) has also been a key concern. Citizenship has referred to the relationship that binds individuals to particular states and their nations. This relationship has been challenged by migration and hence is inextricably bound to its understanding. As Hannah Arendt famously remarked, "sovereignty is nowhere more absolute than in matters of emigration, naturalization, nationality, and expulsion" (1973: 278). Terms like immigration and emigration say something about our interests and position relative to particular states and their respective imagined communities. A more detached transnational approach helps us make sense of the movement of people across territorial borders without succumbing to the tyranny of our particular national affiliation and affective ties.

Immigration: Health and Mortality

Abstract

Over the past 50 years, the immigrant population in the United States and many other high-income countries grew rapidly and became increasingly diverse. Consequently, the study of immigrant health and mortality has become an important area of social science and epidemiological research. Immigrants tend to be healthy at time of arrival, but favorable health profiles tend to erode with increased duration in host countries and continue to deteriorate in the second generation. There is, however, considerable heterogeneity in these overall patterns.

Introduction

The study of immigrant health and mortality has never been as important and interesting as it is now. The most straightforward reason is that migration has increased tremendously over the past half-century, thus creating larger immigrant populations living in many countries throughout the world. For example, the most recent US population estimate suggests that 40.4 million individuals are immigrants, accounting for over 13% of the total population; the next largest immigrant population is in Russia, with just over 12 million immigrants (Pew Hispanic Center, 2013). Overall, it is estimated that 215.8 million people in the world are now living outside of the country in which they were born (Migration and Remittances Factbook, 2011). But beyond the issue of the increasingly high volume of migration, the study of immigrant health and mortality is more compelling than ever because: (1) immigrants are generally a very healthy group of people upon arrival in their new country; (2) immigrants face a challenging process of adjustment to life in a new country that is at the same time potentially harmful and beneficial to their health; and (3) immigrants are a very diverse group, characterized by differences in country/region of origin, skin color and racial identity, socioeconomic status, type of visa, legal and citizenship status, age of entry, duration in the host country, geographic location in the host country, and more. As such, the study of immigrant health and mortality focuses on diverse groups from a wide range of sending countries and measures their health and mortality patterns both shortly after arrival and throughout the life course.

This article reviews basic definitions that are important in this area of study, briefly examines the historical development of immigrant health scholarship, discusses methodological issues and challenges in studies of immigrant health and mortality, reviews current knowledge in the area, and closes with a discussion of future research directions. We focus our discussion on immigrant health and mortality in the US, both because of our own expertise and because the rapidly increasing number of immigrants living in the US since 1965 has resulted in an explosion of immigrant health research in this country. We also incorporate literature on immigrant health and mortality from outside the US as appropriate. Our focus is largely population-based research for the whole US, rather than specific small-scale studies of immigrant health among immigrant groups in particular communities, because our intent is to provide an overview of scholarship and findings in the area rather than diverting attention to particular geographic communities or groups of immigrants. Finally, we devote our attention to mortality, physical health, and health behavior; due to space limitations, we do not address research on mental health.

Key Definitions

This area of study includes several key concepts that are used on a frequent basis and which therefore deserve definitional clarity prior to the discussion of key research findings.

Migration: A general concept that characterizes individuals or groups who make permanent changes in residence across some political or administrative boundary (Swanson and Stephan, 2004). There are a number of types of migration, of which immigration is just one.

Immigration: The permanent movement of individuals across national boundaries to live in a receiving (or host) country; such persons are termed immigrants (Brown and Bean, 2005).

Emigration: The movement of individuals who leave a particular country and cross-national boundaries to permanently live elsewhere (Brown and Bean, 2005). Emigrants are not usually a focus of research because they no longer live in the country that is being studied and it is therefore very difficult to gather data on them.

Nativity: The distinction between persons who are born outside of the country in which they are living (i.e., foreign-born) and persons who are born in the country in which they are living (i.e., native-born) (Swanson and Stephan, 2004). In this article and most literature in this area, the terms foreign-born and immigrant are used interchangeably.

Health selection: The immigration of especially healthy individuals to a destination country, as well the emigration of especially unhealthy individuals back to their home countries (Akresh and Frank, 2008).

Epidemiologic paradox: The unexpected finding in which the health and mortality patterns of US Hispanics were found to be much more similar to those of Whites than Blacks

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31058-3

although socioeconomically, the status of Hispanics was closer to that of Blacks (Markides and Coreil, 1986). The epidemiologic paradox is now often referred to as the Hispanic paradox or Hispanic health paradox.

Immigrant incorporation: The extent to which immigrants are socially, economically, and culturally integrated into the host society (Treas and Batalova, 2009).

Historical Development

There is a long history of studies in public health, epidemiology, and demography that examines the health and mortality patterns of immigrants, some of which make comparisons to both nonmigrants in the origin countries and native-born persons in the host country. Kasl and Berkman (1983) provided an early review of the area. Perhaps most notable, they describe the classic Japanese–American Coronary Heart Study, which found that Japanese immigrants living in California had significantly higher rates of myocardial infarction (i.e., heart attack) and death from coronary heart disease than Japanese immigrants living in Hawaii, who in turn had significantly higher rates than Japanese individuals living in Japan. This study, as well as other similar epidemiologic studies of particular immigrants groups living in particular communities, provided some of the best early evidence that the initial health patterns of immigrants tend to be quite favorable, but less so with increased duration of residence in the host country.

As the number of US immigrants from Latin America (particularly Mexico) grew larger following the Immigration and Nationality Act of 1965, the scientific community gave increasing attention to the health of the Hispanic population. A classic paper by Markides and Coreil (1986) reviewed the literature on Hispanic health and identified more favorable health patterns and lower rates of mortality among this population than might be expected based on their low socioeconomic status; they termed this unexpected pattern the epidemiologic paradox. They further suggested that health selectivity among the immigrant portion of the Hispanic population might be a key explanatory factor for this paradox. The epidemiologic paradox has continued to be the defining theme of literature on Hispanic health in the US, and immigrant health selectivity continues to be a powerful, albeit partial, explanation for the relatively favorable health and mortality patterns of the Hispanic population (Markides and Eschbach, 2011). A great deal of research work in the US continues to focus on the health of Hispanic immigrants, as well as on their second and third generation descendants.

More recent strands of public health, epidemiologic, and demographic research have increasingly given attention to the health and mortality patterns of Asian, Middle Eastern, African, Caribbean, and Eastern European immigrants as well, reflecting the diversity of immigration to the US and other countries (Singh and Hiatt, 2006; Sole-Auro and Crimmins, 2008). This literature also has increasingly taken into account diversity in terms of the geographic settlement of immigrants, the type of visa (e.g., work, family) by which immigrants enter their new countries, and how the gender and socioeconomic status of immigrants influences their incorporation into the host society and their health behaviors and health patterns over time (Treas and Batalova, 2009). Innovative research designs also increasingly take into account data from both sending countries as well as the host society (Landale et al., 2000; Riosmena et al., 2013). In short, this literature has become progressively sophisticated over the last two decades, reflecting an increasingly diverse immigrant population living in a very complex social, legal, and health context. Recent systematic reviews of the immigrant health literature are available in several outlets (Kandula et al., 2004; Loue and Sajatovic, 2012; Treas and Batalova, 2009).

Methodological Issues

The study of immigrant health and mortality patterns is very challenging for a number of reasons. First, by definition, immigrants are people who are geographically mobile. But in addition to the immigration process itself, immigrants may also move a number of times before becoming settled in the host country; moreover, immigrants may continue to travel back and forth to their country of origin and even decide to emigrate at some point in their lives. The study of mobile populations is always more difficult than the study of nonmigrants, simply because geographic mobility makes it more difficult for researchers to survey such individuals and follow them over time. An example of geographic mobility that poses a challenge for mortality researchers is the fact that some immigrants to the US may return to their country of origin when they become elderly and/or sick. This pattern of emigration results in such individuals dying in their home countries instead of in the US. Because the deaths of such emigrants are not recorded by the US vital statistics system, US immigrants have lower mortality rates than what would actually be the case if such individuals had not emigrated. Some researchers have proposed that this selective out-migration process, termed a 'salmon bias', is the primary reason why Mexican immigrants have lower mortality rates than non-Hispanic White native-born adults in the US (Palloni and Arias, 2004). However, more recent research has demonstrated that this pattern of emigration is not nearly common enough to explain the patterns of low infant mortality (Hummer et al., 2007) or adult mortality (Turra and Elo, 2008) among Hispanic immigrants in the United States.

Second, language issues make the study of immigrant health challenging. Large-scale social and health surveys need to accommodate the various language backgrounds and skills of immigrants; if not, such surveys may either exclude some immigrant populations and/or put the validity of the survey at risk. Further, even when individuals are given language choices when answering a survey (e.g., English or Spanish), questions and response categories may be interpreted in different ways depending on the language used. A classic example is in the Spanish vs English interpretation of the response categories used in the 'self-reported health' question that is commonly asked on social and health surveys. Spanish-speaking Hispanics in the US are more likely to report 'fair' while English speaking individuals are more likely to report 'good', even when they have similar health backgrounds (Angel and Guarnaccia, 1989). Thus, researchers have become increasingly concerned with not only providing surveys in different languages, but also

careful attention to the responses to such surveys across immigrant groups who answer in different languages. More generally, difficulty in the assessment of physical health through standard survey-based research techniques has increasingly led researchers to collect health data through biomarker (e.g., blood, DNA) measures. In the immigrant health literature, Crimmins et al. (2007) showed that biomarker assessed health patterns are not fully consistent with survey assessed health patterns among Mexican immigrants in the US; biomarker assessed health for this group appears to be somewhat worse than survey assessed health.

A third methodological challenge in the immigrant health literature is the assessment of health among undocumented immigrants. Below, we briefly discuss that this is a key area for future research, given the large size (i.e., 11 million people in the US), low socioeconomic status, and precarious status of this subpopulation of immigrants. To date, the documentation of the health, health behavior, and mortality patterns of this immigrant subpopulation has been nearly impossible on a large scale because of the legal and ethical difficulties in contacting, surveying, and accurately measuring them.

Finally, a fourth methodological challenge lies in understanding and measuring the dynamic character of the immigrant population. While 'the immigrant population' has been and will continue to be defined by the fact that they are individuals who were not born in the country under study but now permanently reside there, this does not mean that this population is static. Two key points are worth considering. First, the geographic, demographic, socioeconomic, legal, and health characteristics of new immigrant arrivals is dynamic; in other words, new cohorts of immigrant arrivals have the potential to be quite different from previous cohorts – a dynamism that researchers must consider when assessing health and mortality patterns of 'the immigrant population'. Feliciano (2005), for example, provides a thorough documentation of the changing educational composition of immigrant arrival cohorts to the US during the twentieth century. Second, in a similar vein, there is no single trajectory that adequately portrays the life course of immigrants. For example, immigrants may experience an economic context in the host society that is flourishing or stagnating, or they may encounter a generally receptive or hostile receiving community/country. The dynamic characteristics of immigrants along with the dynamic context of life in the host country both need to be taken into consideration when assessing the health and mortality patterns of the immigrant population. Effectively doing so is a very tall order.

Key Findings

Immigrants face numerous challenges throughout the migration process that potentially impact their health in the host country. Even before embarking on their journey, immigrants, who most often originate from low-income countries and migrate to high-income countries, are exposed to health risks endemic to their countries of origin. Once they reach their destination, immigrants may experience difficulties accessing healthcare and other health-related resources because of barriers in socioeconomic status, legal status, and language skills. Despite these challenges, US immigrants nonetheless tend to fare better than the native-born population across a variety of health outcomes, including overall life expectancy. In the following sections, we review current evidence regarding mortality, physical health, and health behavior patterns.

Mortality

Mortality rates are important indicators of population health because they are objective and generally well measured. Literature in this area most commonly shows that immigrants exhibit lower mortality rates compared to the native-born population. Infant mortality rates are lower among women who are foreign-born compared to those who are native-born. Hummer et al. (2007) showed that infants born to Mexican immigrants in the US have a 10% lower mortality rate than infants born to US-born White women and about a 20% lower mortality rate than infants born to US-born Mexican-origin women. Similarly, infants of Black, White, and several major Asian immigrant groups also have lower mortality rates than their US-born counterparts (Hummer et al., 1999). The largest infant mortality advantage is held by Black and Filipino immigrant women, whose infant mortality rates are 44 and 40% lower, respectively, than their native-born coethnics.

However, as foreign-born women reside longer in the United States, their risk of infant mortality tends to increase. In an innovative analysis of infants born to Puerto Rican women both on the island of Puerto Rico and on the US mainland, Landale et al. (2000) demonstrated that infants born to island-born Puerto Rican women have a very low risk of infant mortality when the island-born women first migrate to the mainland US – in fact, much lower than infants born to mainland-born Puerto Rican women. However, after island-born women reside on the mainland for 15–20 years, their infants are characterized by a mortality rate just as high as that of the mainland-born Puerto Rican women. Clearly in this case, the infant mortality advantage found among new Puerto Rican immigrants wears away after women live on the mainland for a couple of decades and becomes a disadvantage among the second and higher generation Puerto Rican women living on the mainland.

A general immigrant advantage in all-cause US adult mortality is also well documented. Singh and Hiatt (2006) found that immigrants have a 19% lower all-cause, age-adjusted adult mortality rate than their native-born counterparts. As such, immigrants are expected to live about 3 years longer, on average, than US-born individuals. The nativity differential is largest for Blacks and Hispanics: compared to their native-born counterparts, foreign-born Blacks and Hispanics display 52 and 26% lower all-cause adult mortality rates, respectively (Singh and Siahpush, 2002). For Black and Hispanic immigrant men, these lower mortality rates translate into life expectancy levels that are 8.1 and 3.8 years longer, respectively, than their US-born counterparts (Singh and Hiatt, 2006). The immigrant advantage in mortality differs to some degree by gender and cause of death. Singh and Siahpush (2006) demonstrated that foreign-born men exhibit a 23% lower all-cause mortality rate and live 4.0 years longer, on average, than US-born men. The immigrant advantage for women is somewhat narrower: foreign-born women exhibited a 16% lower mortality rate than US-born women, translating

into a 2.6-year life expectancy advantage. Finally, immigrant mortality advantages tend to be widest for causes of death associated with cigarette smoking, such as lung cancer, respiratory diseases, and cardiovascular diseases. Immigrant mortality rates also tend to be significantly lower than native-born persons for deaths due to homicide and suicide (Singh and Siahpush, 2002).

Evidence of an immigrant advantage in mortality and life expectancy is not unique to the US. For example, ethnic Germans who migrated from the former Soviet Union to Germany display significantly lower mortality rates compared to that of the general German population (Ronellenfitsch et al., 2006). In Canada, immigrants experience significantly lower mortality rates than those of native-born Canadians. Canadian male immigrants have an all-cause mortality rate about 23% lower than native-born men, while foreign-born Canadian women exhibit a 17% lower mortality rate than their native-born counterparts (Ng, 2011). However, age-adjusted mortality rates among Canadian immigrants are higher among persons with longer duration in the new country. For instance, immigrant men living in Canada for less than 10 years have an all-cause, age-adjusted mortality rate about 20% lower than those who have been in the country for 10–20 years and about 30% lower than immigrants who have been in Canada more than 20 years. Similar patterns were found for Canadian immigrant women. Although the mortality rates of the most established Canadian immigrants were still lower than those of similarly aged native-born Canadians, the mortality rates for immigrants can be described as converging to those of the native-born with increased duration in the country.

Immigrant mortality patterns in the UK are not as consistently favorable as found in the US and Canada. An influential paper by Marmot et al. (1984) found that foreign-born men from Poland, Italy, India, and the Caribbean have lower mortality rates than men born in the UK. In contrast, Irish immigrants and all immigrant women except those born in Italy were found to have higher mortality rates than native-born UK women. More recent research from the UK found that foreign-born Indian men, Eastern European women, and both female and male immigrants from China and Hong Kong exhibited significantly lower mortality rates than the national averages. However, immigrants from Ireland and Africa, men from Bangladesh, and women from India and Pakistan had mortality rates that were significantly higher than the national average (Wild et al., 2007). Thus, while immigrant mortality patterns are generally favorable to native-born populations in most contexts that have been examined to date, researchers must also consider the diversity of patterns exhibited among national origin groups and by gender.

Physical Health and Health Behaviors

A large body of literature documents nativity differences across a variety of physical health and health behavior measures for individuals of different ages who immigrated from different countries. We touch only briefly on key findings here; indeed, it is a very large body of literature. In general, immigrants have quite favorable physical health and health behavior patterns upon entry into receiving countries, but those favorable patterns tend to dissipate with increased number of years spent in the country. Moreover, the health status of second and third generation persons tends to be less favorable than that of the immigrant generation.

Hamilton et al. (2011) comprehensively investigated whether the prevalence of various childhood health conditions differed for immigrant children in comparison to children of native-born parents within each major US racial/ethnic group. Their results point to a clear pattern of increasing rates of asthma, allergies, learning disabilities, and developmental problems from first (i.e., children born outside of the US) to second (i.e., US-born children of an immigrant parent(s)) to third generation children (US-born children of US-born parents). For instance, only 7.7% of first generation Hispanic children reported asthma compared to 11.9% of second generation and 18.8% of third generation children. Antecol and Bedard (2006) demonstrated similar results for US adults: immigrants were characterized by more favorable patterns of several general measures of health compared to the native-born population.

Within the immigrant generation itself, results from many US studies show that the generally favorable health of new immigrant arrivals tends to become less favorable with increased time spent in the country. Indeed, several groups of researchers have shown that the relatively healthy body mass index (BMI) of immigrant men and women in comparison to the native-born population becomes less favorable with increased duration spent in the United States (Antecol and Bedard, 2006; Singh et al., 2011). The favorable health patterns for newly arrived Asian immigrants (Frisbie et al., 2001) and Hispanic immigrants (Cho et al., 2004) also converge to those of the general population with increased duration in the US.

Singh and Miller (2004) examined several measures of health – including activity limitations, days spent sick in bed, and number of chronic diseases – among a number of racial/ethnic groups by nativity and immigrant duration of residence in the US. Although they found immigrants to have drastically lower odds of poor health compared to their US-born counterparts, immigrants who had been in the United States for fewer than 15 years had even lower odds relative to more established immigrants. For instance, recent Mexican immigrants had 70% lower disability risk than US-born Whites, whereas longer-term Mexican immigrants had 50% lower disability risk. More recently, several studies have examined rates of disability among older immigrants both in the US and in a number of European countries. Interestingly, health and disability patterns for older immigrants both in the US (Markides et al., 2007) and in 10 European Union countries (Sole-Auro and Crimmins, 2008) appear to be less favorable than native-born individuals in those countries, even though the immigrant mortality rates in those countries are lower than those of the native-born population. Such a pattern could occur if older immigrants living in these countries have spent many years working difficult jobs that result in disabilities in old age, while continuing to exhibit low rates of mortality from chronic conditions such as heart disease and cancers.

New immigrants also tend to have more favorable health behaviors than the native-born population, which may be a key contributor to their general health and mortality advantages. One of the most well-documented health behaviors is cigarette smoking. In the US, cigarette smoking prevalence is much

lower among immigrants than the US-born population. Lariscy et al. (2013) recently found that foreign-born Hispanic men and women are 65 and 85% less likely, respectively, than their US-born White counterparts to have ever used cigarettes. The same pattern holds true for other immigrant groups as well. According to research by Singh and Siahpush (2002), Hispanic, Black, and Asian immigrants are 63, 75, and 46%, respectively, less likely to smoke cigarette than US-born Whites. Foreign-born Blacks and Hispanics are also significantly less likely than their US-born counterparts to use cigarettes. Blue and Fenelon (2011) recently estimated that low levels of smoking among US immigrants accounted for 50–75% of the immigrant mortality advantage relative to US-born adults. Moreover, US immigrants are also less likely to drink alcohol at all levels of consumption than their native-born counterparts (Lopez-Gonzalez et al., 2005). Lower levels of alcohol use among immigrants, particularly at high levels of consumption, could help explain lower levels of mortality due to certain cancers, homicide, and suicide in comparison to the native-born US population.

While extensive literature points to a general immigrant health advantage in comparison to the native-born population, the health of immigrants – particularly in the United States – tends to deteriorate as they become more incorporated into the host country. In the population-based literature, length of stay in the new country is often used as a proxy for immigrant incorporation, although some studies also use indicators such as whether or not immigrants have naturalized (i.e., obtained US citizenship). But no matter what indicator of incorporation is used, most studies find that recent immigrants have the most favorable health and mortality patterns while those who are more incorporated into the host society have health and mortality profiles that are much closer to or even worse than those of the native-born population. The health of immigrants has also been shown to deteriorate as they adopt detrimental health behaviors over time. Immigrants who have been in the United States longer are more likely to be cigarette smokers and heavy consumers of alcohol. Lopez-Gonzalez et al. (2005) also show that the association between immigrant incorporation and health behavior is stronger for immigrant women than men; that is, the very healthy behavior of new immigrant women compared to US-born women becomes much more like US-born women for immigrants who have resided in the US for more than 15 years, are naturalized citizens, or both.

Other research has focused on patterns of BMI as immigrants become incorporated into the United States. While immigrants in general arrive in the United States with BMIs significantly lower than that of the native population, their BMI increases with longer duration in the new country. Antecol and Bedard (2006) found that the BMI of US immigrants who have been in the country for 15 years is similar to that of the native-born population. This pattern is more apparent for immigrant women, especially Hispanics, than men, who never fully reach the BMI of US-born men. Moreover, increases in BMI among US immigrants appear to be especially concentrated among those who are poor and arrive from low-income countries (Frank and Akresh, 2013). Thus, as the evidence suggests, immigrant advantages in health diminish with incorporation, but perhaps especially so for those who live in poverty in the United States.

Theoretical Explanations

Health Selection

Positive health selection offers one explanation for the health and mortality advantage of immigrants. According to this theory, individuals who choose to migrate are healthier than those who remain in sending countries. Health selection is commonly assessed by comparing the health status of immigrants in the receiving country and nonmigrants in the country of origin. In the case of positive health selection, we would expect immigrants to have much better health status than those who did not migrate. Several studies have found support for immigrant selectivity, particularly among men, in Europe and the United States. In the most comprehensive study of immigrant health selectivity in the US to date, Akresh and Frank (2008) found that immigrants from all countries and regions studied reported more favorable health in comparison to persons in the sending countries or regions from which they originated. The early classic study by Marmot et al. (1984) echoed this finding in the UK by documenting lower mortality rates among almost all groups of male immigrants in comparison to same aged men in their countries of origin.

Health selection, as with other forms of selection among immigrants, is influenced by a variety of micro- and macro-factors ranging from individual resources to economic climate and national policy. Thus, the degree of health selection varies quite extensively across immigrant groups and a couple of key patterns have emerged in this literature. First, immigrant human capital is important to the health selection process. In a theoretical model of health selection, Jasso et al. (2004) stipulate that potential migrants evaluate the costs and benefits of migration such that the gains – primarily, economic – need to outweigh the costs associated with migration. As such, those with greater human capital resources – such as high levels of educational attainment – are often able to reap more benefits from migrating. Superior health status may also impact this decision-making process by increasing the real or perceived earning potential of immigrants, thus acting as an impetus for healthier individuals to capitalize on greater monetary gains through migration. Indeed, Akresh and Frank (2008) found that immigrants who came to the US with employment visas were more likely to have been selected on good health than those who came to the US under the family reunification and refugee visa programs. More directly, Feliciano (2005) examined education selectivity among immigrants from the top 32 sending countries to the United States. Her results indicate that there is positive educational selectivity among immigrants from 31 out of the 32 migrant-sending countries (the one exception is Puerto Rico, a US territory). Given the well-documented association between education and health, the relationship between educational selectivity and health selectivity may also be closely intertwined.

Second, health selectivity among immigrants is especially salient among those who come from geographically distant sending countries. Akresh and Frank (2008) found that Mexican immigrants have the lowest level of positive health selection compared to immigrants from more distant countries, while immigrants from several African and Asian countries were found to report much better health than the average level in their sending countries. However, that is not to say Mexican

immigrants do not exhibit positive health selectivity. Crimmins et al. (2005) used height, an anthropometric measure that acts as a proxy for childhood health, and found that Mexican immigrants in the US are significantly taller than nonmigrants in Mexico. Nevertheless, geographic distance between the sending and receiving country may very well be related to individual migration costs that have been theorized to influence the positive health selectivity of immigrants.

The positive health selectivity of immigrants is further reinforced through host country policies that screen and potentially reject the entry of immigrants who have health problems. Perhaps even more important, the immigration process can be physically taxing for those migrating on an undocumented basis. Simply put, unhealthy people are much less likely to undertake an arduous and dangerous journey.

Immigrant Incorporation

Immigrant incorporation has been used in this article to refer to the difficult process of social, legal, cultural, and economic adjustment to the host society. Most often in the immigrant health literature, the process of incorporation involves the downward health trajectory of immigrants after their selectively healthy arrival. As documented above, immigrants have been found to adopt the poor health behaviors common in the host country (Lopez-Gonzalez et al., 2005). After a decade or so in the United States, for example, the initially lower levels of cigarette smoking, alcohol consumption, and obesity that characterize immigrants converge to those of the native-born population. These health behaviors are certainly important contributors to the worsening mortality and morbidity outcomes among immigrants with longer duration of time spent in the host country.

However, the process of incorporation is much more complicated than health behavior changes. Increasingly, researchers in this area are considering the often poor working conditions of immigrants: the legal, social, and neighborhood contexts in which immigrants live; the social and neighborhood contexts in which immigrants are embedded; and the racial identity and socioeconomic status that characterize different groups of immigrants (Abraido-Lanza et al., 2006). Some of these dimensions of incorporation, such as a hostile legal context, can have negative health effects, while others, such as the social support found in neighborhoods with high concentrations of immigrants, can have positive health effects. The idea that the immigrant incorporation process is not linear or straightforward and involves a complex set of dimensions is increasingly gaining a foothold in this area of study.

Jasso et al. (2004) further posed a serious challenge to the theoretical model of negative immigrant incorporation. They suggest that the health of immigrants may actually improve over time through the economic gains achieved through the labor market. Using longitudinal data, the authors examined the relationship between income and short-term health changes for new legal immigrants in the United States. They found that legal immigrants experienced a substantial income gain after moving to the US, and that this income change has a significant positive impact on their self-reported health status. While these short-term results do not capture longer-term incorporation effects that may be both positive and negative, the authors argue that health benefits resulting from positive income change may not only persist but actually increase for new immigrants over time. Clearly, then, the incorporation process that immigrants experience must be considered as multidimensional and complex; it cannot simply be measured through simple indicators like duration of residence in the host society.

Future Research Directions

As discussed above, the immigrant population is not only growing in the US and many countries, but it is also very diverse and dynamic. Future research must increasingly consider this diversity because patterns of health, health behavior, and mortality for the entire immigrant population may vastly differ for various subpopulations. Consider, for example, highly educated and skilled immigrants coming to work in professional occupations in comparison to poor refugee immigrants from a war-torn country who are simply moving to survive. The heterogeneity in immigrant backgrounds must be considered in order to develop an accurate picture of immigrant health and mortality.

Second, very little is known about the health, health behavior, and longevity of the estimated 11 million undocumented immigrant population in the US (Pew Hispanic Center, 2013). Research on the undocumented immigrant subpopulation is understandably thin because they may be less likely to trust and participate in private-, government-, or university-based survey initiatives than the general public. That said, undocumented persons do participate in population-based surveys, usually without being asked to divulge their legal status, and the population research community has gotten quite skilled in using such surveys to estimate the size and basic characteristics of the undocumented population. However, because of the relatively young age structure of the undocumented immigrant population, their health and mortality patterns have not been a topic of much research. Clearly, that should change. Indeed, many or most undocumented immigrants are thought to work in very difficult jobs with low pay, live very stressful lives with high levels of fear, have limited access to social and/or health services, and may face serious discrimination in social institutions and at the individual level (Massey, 2013). Those are not favorable characteristics for long-term good health or for the health of native-born children of undocumented immigrants. Many social scientists worry that the difficult and fearful social and legal context in which undocumented immigrants and their children live will one day have dire health consequences for the lives of these individuals, almost all of whom are living and working in the host country in the attempt to better their lives while serving as a source of needed labor. A better understanding of the health, health behavior, and mortality patterns of the undocumented immigrant population should be an important topic of research in this area in the near future, even though such research will undoubtedly be very challenging to conduct.

Finally, as discussed over 30 years ago in a seminal article (Kasl and Berkman, 1983), the ideal research design for the study of immigrant health and mortality patterns involves a three-way comparison of immigrants in the destination

country to both persons in the origin country(ies) who did not migrate as well as to native-born persons in the host country. Most often, research designs do not make such three-way comparisons and instead only focus on a comparison between immigrants and the native-born population in the host society. This unfortunately ignores nonmigrants in the origin country(ies), from where the pool of immigrants came. However, a few innovative studies in this area have made such three-way comparisons, allowing researchers to understand both the ways that immigrants differ from demographically similar people in origin countries who do not migrate as well as to how they differ from demographically similar native-born people in the host country (e.g., Landale et al., 2000; Riosmena et al., 2013). But we also urge researchers to think about research designs in a longitudinal framework that follow individuals over time to best determine how the health behaviors, health trajectories, and mortality risk of individuals in these three subgroups unfold. It is only in the context of such a longitudinal, three-way design that the research community will truly be able to understand how the health and mortality patterns of immigrants differ from those of their nonmigrant and native-born counterparts, both at the time of immigration and for many years thereafter.

Immigration Policy

Sofia A Perez, Boston University, Boston, MA, USA

Abstract

Immigration policy includes all of those policies whereby states control the influx of persons who want to establish residence within their borders: rules regarding rights of access to the territory (entry and residence), permission to participate in the labor market (work permits), the rights of asylum seekers and refugees, the rights of immigrants to bring family members (family reunification), and rules for the acquisition of citizenship by immigrants and their family members (naturalization). Such rules may be linked to the notion of humanitarian 'rights' of individuals (as in the case of asylum and family reunification law) or respond to selective state objectives (such as demographic and labor market needs). Immigration policies can be traced back to rules whereby modern states defined who held citizenship rights in the aftermath of the French Revolution. The most important distinction here is that between states followed the rule of *jus solis* (birthright citizenship) versus those following *jus sanguinis* (acquisition of citizenship by descent). Labor shortages that emerged during the industrial revolution led to the introduction of labor recruitment schemes by the United States and several European countries during the late nineteenth century and again after World War II. Together with decolonization, they provided a strong impetus for migration from poorer to richer countries starting in the mid-twentieth century. Following the economic crisis of the 1970s, many countries ended these labor recruitment schemes. The crisis in the former Yugoslavia also led to a tightening of rules regulating applications for asylum. Family reunification hereby became the dominant avenue for immigration into advanced industrialized countries. The 1990s and 2000s saw the introduction of new selective immigration policies aimed at recruiting specialized labor and high-skill professionals in a number of industrialized countries. The overall tenor of immigration policy is difficult to measure because similar rules will cause higher rates of immigration into some countries and lower rates into others depending on other factors that push people to migrate out or their countries of origin or attract them to migrate given conditions in destination countries (referred to as 'push' and 'pull' factors in the literature on migration).

Introduction

The term *immigration policy* encompasses all those measures by which a state regulates the influx of persons, in particular those who want to establish residence in their territory either temporarily or permanently. Rules that governed the *right of abode* of free tradesmen in medieval times and those that served to define *citizenship* (also referred to as *nationality*) in Europe following the French Revolution represent early points of reference for such policy (Brubaker, 1992). Today, immigration policy is commonly divided into four categories: rules that allow work-based immigration, those related to humanitarian concerns such as political asylum and family reunification, and those that govern the acquisition of citizenship through naturalization. Policies aimed at integrating immigrants into host societies (immigrant integration policy) may be distinguished analytically from strict immigration policy (those that govern entry and abode). But such policies, along with many other aspects of social, educational, and labor market policies, can also affect migration flows.

Types of Immigration Policy

The legal and administrative framework of different countries affects the ways in which immigration policies are categorized. Different historical trajectories including the timing of state formation, its relationship to the extension of political and social rights (citizenship) and to socioeconomic and geopolitical developments behind major migratory flows all influence how modern immigration policy is framed and regulated across countries. Nonetheless, post-World War II developments such as international humanitarian conventions and European integration mean that immigration policies are typically categorized in terms of whether they relate humanitarian rights (to political asylum or family life), labor recruitment (work-based immigration), or the acquisition of full citizenship rights by immigrants (naturalization). These categories are also commonly used to quantify immigration statistics (see **Figure 1**). Whereas much early migration was driven by labor recruitment schemes, historical developments (see below) have meant that family reunification has become the dominant basis for immigration into most advanced industrialized economies with work-based migration playing an important role in only a few OECD countries and asylum-based migration subject to increasing restrictions. However, the last set of enlargements of the EU have also produced large-scale migration based on free movement within the area (as illustrated in **Figure 1**). Acquisition of citizenship rules varies substantially with some countries facilitating a path to citizenship for most permanent immigrants over a relatively short number of years and others imposing far lengthier residency requirements that are harder to meet. Naturalization rates thus also vary significantly among the top destination countries for migrants (see **Figure 2**).

Historical Background

Starting in the nineteenth century, many states began to institute laws to regulate the status of foreigners within their territory, attract immigrant labor, or restrict migratory flows across their borders. Such laws were driven both by political and

geopolitical reasons and by new demographic needs linked to socioeconomic developments (Brubaker, 1992; Bade, 2003: pp. 129–164). Early postcolonial states that put claim to large expanses of land with relatively limited populations – Argentina, the United States, Australia, Canada, or New Zealand – sought to attract European immigrants who brought capital or specific skills to establish their control over territory and promote economic development (Waisman, 1987; Freeman, 1995). Yet the influx of new ethnic groups often produced political backlash, giving rise to *nativist* political movements that led to the adoption of restrictions to labor immigration along ethnic and racial lines. The Chinese Exclusion Act of 1882 and the 1924 National Origins Formula, which defined immigration policy in the United States for many decades, are prominent examples (Zolberg, 2008). In Europe, the seasonalization of agriculture and the industrial revolution produced large cross-border migratory flows that reached a new peak in the late nineteenth century and early

twentieth century. Rapidly industrializing Prussian Germany soon became the main destination country for migrants in Europe, second only to the United Sates, while Italy and the British Isles long held the status as the main country of emigration (Bade, 2003: Chapter 2). During this time, governments introduced early labor recruitment schemes, such as the Prussian state's regulation of labor migrants from Poland starting in the 1880s and France's interwar regime of bilateral treaties to import workers for key economic activities from Southern and Eastern European states (Bade, 2003: pp. 157–164; Noiriel, 1988; Lewis, 2007). In most Western countries, policies turned more restrictive during the course of the interwar period as national labor unions gained power and economic conditions worsened.

Reconstruction and growth during the post-World War II decades in Europe also hinged on migratory flows from South and South Eastern Europe to the main Continental economies (in particular France, Germany, and the Netherlands). This period marked the heyday of foreign labor recruitment schemes – commonly known as *guest worker* programs – which allowed domestic employers to recruit foreign workers without envisioning a path to permanent settlement or the acquisition of citizenship. Germany and Switzerland, in particular, enforced strict rotation of workers as a means to limit *de facto* settlement. Decolonization was the second main driver of immigration into Europe during this period, as former colonial powers (in particular Britain and France) extended citizenship to former colonial subjects. In the case of France, whose citizenship laws were based on the principle of *jus solis*, the children of immigrants typically acquired nationality at birth or once they had reached legal age. (Nonetheless, French nationality law has been changed repeatedly since the 1980s to raise the residence requirements for children born in France who do not also have one parent who holds French citizenship.) In other countries whose citizenship traditions were based on the tradition of *jus sanguinis*, notably Germany, Switzerland, and Austria, courts subsequently extended rights of residence (although not of citizenship) based on humanitarian considerations. Such rights include the right of political asylum, enshrined in the 1951 Geneva convention on the Rights of Refugees, and the principle of family reunification, which was included in Article 16 of the United Nations' 1948 Universal Declaration of Human Rights and in many national constitutions.

In the United States, where birthright citizenship was enshrined in the Constitution, the domestic struggle for civil rights and equality led to a new immigration law in 1965 that abolished the country of origins quota system established in the 1920s (Safran, 1997). The quota system had heavily favored immigration from Northern Europe (as opposed to Southern and Eastern Europe, Asia, and Africa). The 1965 act allowed for permanent immigration based on work, but it also imposed an overall annual quota system requiring that 74% of visas be reserved for family reunification cases. In the case of Japan, citizenship by descent was the norm, and immigrants who were not born to Japanese parents (including conscripted laborers from China and Korea brought over during World War II) were left in a legal limbo by the 1952 Japanese Immigration law. Nonetheless, Japan did allow for a significant number of refugees from Indochina in the late 1970s and ratified the Geneva Convention on the status of Refugees in 1981. Canada and Australia both maintained liberal immigration laws to encourage the settlement of foreign citizens during the postwar period.

Recent Developments

If the overall trend in the 1950s and 1960s was toward relatively liberal immigration policies, the period following the first OPEC oil shock was marked by abrupt moves to restricted immigration into many advanced industrialized countries. Germany suspended its labor recruitment schemes in 1973, followed by France, Sweden, and the Netherlands, and thereafter immigration into most of Europe was largely restricted to family reunification and asylum cases (Perez, 2011). In the United States, the system adopted in 1965 – allowing for work-based immigration but prioritizing family reunification – was maintained. Political backlash to large-scale immigration from Mexico and Central America led individual states to pass restrictions on the rights of immigrants starting in the 1990s. The hallmark of this trend was California's proposition 187, a ballot initiative passed by public referendum in 1994 that denied health care and public education to undocumented immigrants in the state. The measure was subsequently repealed by a federal court. Nevertheless, Proposition 187 marked the beginning of a wave of efforts by several other states in the United States to encourage so called self-deportation of immigrants through laws that made life inhospitable for them.

In the case of Europe, the break up of Yugoslavia and the massive exodus of refugees from the Balkans at the end of the 1980s led to a second wave of restrictions during the 1990s. The German parliament reformed the country's Basic Law in 1993 restricting the right of asylum so that individuals that had passed through a third country that was deemed 'safe' by the German legislature could no longer apply for asylum. The 'safe third country' rule was in turn adopted by other EU member states. Following the 1997 Treaty of Amsterdam – which opened the way for EU wide immigration policy – it was also adopted as EU law. It has since that time also become part of asylum law in many other countries beyond the EU.

One consequence of the restriction of legal immigration since the 1990s has been the rise in the number of undocumented – also referred to as irregular or illegal – immigrants in many advanced industrialized countries. This includes not only persons who have entered clandestinely but also individuals whose visas have lapsed and who continue to remain in a country. Undocumented immigrants live precarious lives, facilitating the growth of the informal economy and presenting a threat to wages and labor standards. Some states have opted to address the situation of undocumented immigrants through regularization (also known as 'legalization,' 'normalization,' or 'amnesty') allowing those who are deemed to be deserving for humanitarian reasons or those who have long stays to legalize their status. Regularization can occur either through ongoing mechanisms that allow persons with long stays to apply for permanent residence or as one-off programs that allow persons who entered prior to a particular date to apply for legal status (Baldwin-Edwards and Kraler, 2009; OECD, 2011; Brick, 2011). The latter approach, however, is often criticized by those who believe regularization campaigns reward illegal behavior and serve as an implicit inducement to illegal

immigration (Levinson, 2005). Many scholars have also noted the growing tendency by governments and the media to frame immigration policy in terms of its relationship to national security and crime since the 1990s, a phenomenon referred to as the *securitization* of immigration policy (Huysman, 2000; Kostakopoulou, 2000; Muller, 2004; Tsoukala, 2005). This tendency was accentuated by the 11 September 2001 attacks in the United States (Faist, 2001; Levy, 2005; Rudolph, 2006; Messina, 2007).

Another development in the past two decades has been the gradual move away from 'rights'-based immigration policies based on humanitarian and entitlement principles to more 'selective,' 'points-based,' or 'demand-based' immigration policies, which seek to change the profile of immigration in favor of migrants that have specific, and in particular higher, skills (Balch, 2010; Cerna, 2009; Perez, 2011). Canada, a country that pursued a very open immigration policy in the postwar period, launched a *points*-based system to give priority to skilled workers as early as 1967. Japan adopted a skills-based immigration law in 1989, allowing for entry of high-skilled workers and professionals while officially not allowing the entry of low-skilled workers and, in 1993, also introduced a trainee system under which unskilled workers are able to migrate to Japan to work in agriculture, fishery, construction, and other sectors facing labor shortages. In Europe, the Labor government of Tony Blair introduced a 'managed migration' during the late 1990s to promote the immigration of persons that met specific labor market needs, and in 2007, Gordon Brown's Labor government passed a new 'points-based' immigration law that was largely modeled on the Canadian example. These policy changes allowed for a significant rise in work-based immigration into the United Kingdom during the 2000s following two decades in which net migration growth had been held close to zero by Conservative governments.

The two principal destination countries into the EU in the late 1990s and 2000s by far, however, were Italy and, in particular, Spain (Perez, 2011), two countries that had previously served as major suppliers of immigrant labor to the rest of Europe. Clandestine immigration from the African continent and the Balkan region into these two states received a great deal of media attention both domestically and internationally. But most immigrants into Spain and Italy arrived by normal border crossings, either by land or air. By contrast to the rest of Western Europe where immigration was virtually limited to family reunification since the early 1990s, Spain and Italy, along with the United Kingdom, also had a much larger component of work-based immigration and pursued specific labor market objectives with their policies (Perez, 2011). However, following the 2004 and 2207 EU enlargements, immigration from outside the EU was displaced by intra-EU migration from new to old member states, and such intra-EU migration does not lend itself to selectivity as member states are committed by law to allow free movement of workers within EU borders. The EU Commission has consistently advanced the view that EU member states need to adopt more open, if targeted access to third country nationals to address skill shortages and the problem of aging populations and high dependency ratios. With this in mind, it submitted a proposal for the issuance of new EU-wide permanent work permits – called Blue Cards – to compete with the U.S. Green Card program and skills-based immigration schemes in Canada and Australia. The proposal was adopted as an EU directive in 2009, but it leaves room for member state governments to suspend the issuance of such work permits on the basis of national needs.

In the United States, where immigration continues to be heavily dominated by family reunification, there have also been proposals to strengthen the component of skills-based immigration. The more important debate in the 2010s, however, has centered on the status of a very large number of undocumented workers. Immigrants who apply for work-based permits and seek to obtain permanent residence in the United States often end up in undocumented status because they face an interruption in their employment status during the course of completing the work-based residency applications. Together with clandestine entries and people who overstay tourist visas, undocumented workers featured prominently in the 2008 presidential election and in the subsequent congressional elections, with some politicians offering support for a regularization effort. Proposals for immigration reform that would allow persons with long stays, those who reached the United States as minors, or those who belong to 'mixed-status' families to regularize their status have been the subject of long political debate and became a major issue of contention in the 2012 presidential and congressional elections.

Key Debates: Immigrant Integration and Implications for Welfare States and Labor Markets

Immigration policy across the world has also been strongly influenced by the perceived failures to integrate the children of poorer immigrants in advanced industrialized countries, particularly children of Turkish immigrants in Germany, those of North African descent in France, and hispanic immigrants to the United States (Schain, 2008). 'Downward assimilation' (Portes, 2001), or the tendency for the children of poor immigrants with lower educational backgrounds to get trapped in poor American cities where public education resources are stretched, has been a particular concern in the United Sates. Policies to address integration have ranged along many dimensions (Bauböck, 1995; Favell, 1998; Guiraudon, 2000; Koopmans et al., 2005; Jopke, 2007). One distinction that has received particular attention, however, is that between a multiculturalist approach to integration, consisting of cultural accommodation of new immigrants through such measures as bilingual education or legal accommodation of religious practices, and a more traditional approach geared toward cultural assimilation. Proponents of multiculturalism argue that it serves to combat social exclusion and thereby furthers social integration (Kymlicka, 1995; Kymlicka and Banting, 2006) while opponents believe that it can obstruct integration by leading to self-segregation and the fragmentation of society into ethnic subgroups (Barry, 2001; Goodhart, 2004) or even dependence on welfare support (Koopmans, 2010). One particular argument holds that multiculturalist integration policies tend to become a barrier to socioeconomic integration in countries with more generous welfare spending while they may be of less consequence in countries with less generous systems of social support (Koopmans, 2010). The Netherlands once seen as the paragon of the multiculturalist

approach to integration, but also Sweden and parts of Belgium are often cited as examples of such a 'progressive dilemma' (Goodhart, 2004) because they show less successful employment outcomes among immigrants than do other European countries. However, other authors have observed that countries that pursue multiculturalist accommodation may allow immigrants to develop social capital by way of ethnic networks (ethnic capital) that supports economic integration and that rates of civic and political participation by immigrants in countries pursuing multiculturalist policies are also higher (Fennema and Tillie, 1999; Jacobs and Tillie, 2004). The desirability of such mode of integration, however, is questioned by authors who regard it as a challenge to universalist, liberal values (for instance Jopke, 2008). Yet other authors who place immigration policy in a broader structural context distinguish various *modes of incorporation* which are the result not only of policy but also the particular structure of immigrant communities and their historical relationship to the host country (Portes and Zhou, 1993; Portes, 1995; Bodovski and Benavot, 2006).

The perceived failures to integrate immigrants have led many European countries to impose language requirements as a condition for immigration or the renewal of residence permits. The United States, which does not have an official national language, has not imposed such restrictions, although individual states have passed so-called English only laws that either establish English as the state's official language or seek to prohibit state and local governments from using another language. The policy debate on immigrant integration in the United States has centered heavily on the best way to promote the acquisition of English as a second language among the children of immigrants who have limited English language proficiency, with approaches ranging from education of immigrant children in their native language (commonly referred to as bilingual education) to sheltered language immersion programs (Rossell and Kuder, 2005).

Among economists, there has also been an ongoing debate over the benefits of immigration for overall economic growth and its impact on the wages of different categories of domestic workers, with some arguing that the existing pattern of low-wage immigration, in particular into the United States, hurts poorer domestic workers disproportionally (Borjas, 2003) while others argue that low-wage immigration tends to benefit overall economic growth and allows lower paid native workers to move into better paid work (Card, 2004; Mayda and Patel, 2004; Peri and Sparber, 2008; D'Amuri and Peri, 2010). Another concern raised by both economists and political scientists is the potential impact that immigration may have on support for national welfare states. While some authors have argued that the increased cultural heterogeneity that immigration brings about may undermine support economic redistribution (Freeman, 1995; Alesina and Glaeser, 2004), others have argued that such an outcome is unlikely (Banting and Kymlicka, 2006; van Oorschot and Uunk, 2007).

Problems of Measurement

Efforts to measure the overall tenor of immigration policy – how liberal or restrictive it is across countries – have tended to be elusive because of the multidimensionality character of immigration. Indices covering several policy dimensions, such as work visa and asylum policy requirements, as well as measures of policy change in a more or less restrictive direction have been constructed (Mayda and Patel, 2004; Mayda, 2009; Ortega and Peri, 2009), but they tend to raise questions of validity as they require the coding of cumulative laws across countries and the reference points for immigration laws are often different from country to country. Yet another index developed by the British Council and the Migration Policy group – the Migration and Integration Policy Index (MIPEX) – measures the degree of legal equality that immigrants attain once they have arrived. However, immigration can often be encouraged or discouraged through measures that are not captured in formal laws, such as the time it takes to obtain visas or obstacles to the accreditation of educational degrees. Because immigration policy involves so many different elements, aggregation of policy measures almost invariably involves subjective decisions. More importantly, as in the case of trade policy, a given immigration rule may represent a more or less restrictive depending on factors such as the demand for labor in a particular destination country, transportation costs, or differences in wages between two countries. This complexity has led some authors (see Boussichas and Goujon, 2010) to argue for the use of 'revealed' immigration policy measures that compare actual immigration flows to those that we would expect from nonpolicy, structural determinants (growth, employment, trade openness, and other identified drivers of migration) to tease out the effect of immigration policy.

Conclusion

Immigration policy has gained growing importance and electoral salience over the past two decades in the advanced industrialized world (Givens and Luedke, 2005; Schain, 2008), and political and academic debates regarding the consequences of immigration have become increasingly charged. At the same time, countries with aging populations and high dependency ratios (in particular in Europe but also Japan) face demographic trends that may only be resolved through further immigration. The trend toward more open but selective, work-based migration policies, as typified by the EU Blue Cards program and skills-based immigration schemes in Canada and Australia, reflects such underlying demographic imperatives. However, rising migratory flows from poorer to richer countries also produce strong political reactions, as exemplified by the rise of anti-immigrant parties in much of Europe and the hard-line stance of the conservative Tea Party wing of the Republican party in the 2012 elections in the United States. The great recession has further fed such reaction. In the EU, the impact of EU enlargement allowing for large-scale free movement from new to old member states in the period since 2007 has been to encourage renewed popular resistance to immigration from third countries and to place long-term concerns regarding demographic growth on a back burner. At the same time, the crisis in the Eurozone has reversed long-time trends, leading to renewed emigration (principally of skilled labor) from the European countries most affected by the crisis – some of which paradoxically had become major destination countries for

immigrants in the prior decade – to the rest of the EU as well as to emerging market economies. These most recent developments suggest that the long-term outlook for immigration patterns and immigration policies is likely to depend heavily on broader economic developments in the EU and elsewhere.

Immigration: Political Aspects

Christian Joppke, University of Bern, Bern, Switzerland

Abstract

This article reviews recent cross-disciplinary academic work on the political aspects of immigration, a previously understudied aspect of international migration. A distinction is made between immigration policy (or immigrant selection) and integration policy, reviewing some of the most important theory-guided, explanatory, and comparative works on these topics.

Immigration is the permanent movement of individuals across states, seen from the perspective of the receiving (rather than sending) state. While a 'transfer of jurisdictions' (Zolberg, 1981: p. 5) is thus constitutive of immigration, traditional theories of immigration have surprisingly ignored the state, focusing instead on the economic motivations and social ties that initiate and perpetuate migration flows. The traditional view can be bound, for instance, in this encyclopedia's 1968 predecessor, which discussed 'migration' only under its 'social' and 'economic,' but not political aspects (Petersen, 1968; Thomas, 1968). What since its publication in the late 1990s has remained the state-of-the-art review of migration theories and of the world's major 'migration systems' (Massey et al., 1998) indirectly defends the traditionally nonpolitical migration theories, in arguing that states are in principle incapable of controlling social network-based migration flows (see also Massey, 2001).

While, especially in the United States, the study of immigration continues to be a domain of sociologists and demographers, a major development in the past few decades has been a growing interest by political scientists and political sociologists in the central role of the state, and increasingly of nonstate actors also, in the soliciting, control, and integration of immigrants and immigration. This reflects not only a disciplinary evolution and renewed interest in the state and 'governance' across the social sciences, but also some changing feature of contemporary migration for which the state has become increasingly central. The classic notion of immigration was coined in the 'stateless' period before World War I, when almost 50 million Europeans moved largely unhindered by national entry controls to the Americas and the Antipodes (but for the importance of subfederal controls in nineteenth-century America, see Neuman (1993)). After a brief restrictionist interlude in the inter-War period, the image of 'stateless' immigration was revived after World War II, when the classic settler nations abolished racially motivated restrictions on immigration, and when some northwestern European countries underwent large-scale labor migrations from the South. States already figured prominently for these flows because a conscious change of policy (as in North America or Australia, which abolished its 'White Australia' policy in 1971), bilateral agreements with the governments of sending countries (as in Germany or Switzerland's guestworker migration), or a geopolitically motivated abstention from controlling postcolonial flows (as in Britain, France, or the Netherlands) were necessary to initiate or allow them. However, the involvement of states was invisible because this immigration was wanted or at least passively accepted and considered unproblematic. A typical example of this period is France, where until the late 1960s, immigration from the South proceeded spontaneously and outside the official channels of the *Office nationale d'immigration* but was legitimized after the fact by the routine distribution of residence and work permits (see Viet, 1998: pp. 233–254).

The picture of 'stateless' immigration – though always a fiction – changed radically in the mid-1970s, when under the impact of the first oil crisis and the most serious economic recession after World War II, European states shifted to zero-immigration policies, and when seemingly 'uncontrolled' illegal immigration from Mexico galvanized a restrictionist turn in the United States. Now, 'states' began to matter, either as bulwarks against unwanted immigration (as in the rhetoric of political elites) or as sieves that chronically failed to live up to their restrictionist intentions (as in the account of most academics; see, for instance, the influential 'gap hypothesis' by Cornelius et al. (2004)). In this historical moment, when the central role of the state in international migration became problematic and therefore visible, political sociologists and political scientists discovered 'immigration,' suggesting models to classify and explain states' immigration policies and how the latter derived from – or violated – their sovereignty (Section Explaining Immigration Policies) and investigating the impact of immigration on the membership component of nation-states, which is the topic of a new literature on integration and citizenship (Section Integration and Citizenship). When the previous edition of this encyclopedia went into print, leading demographers and sociologists, the traditional 'owners' of the immigration domain, still thought that the relationship between state policies and international migration, while perhaps considered increasingly important, remained 'under-theorized and little studied' (Massey et al., 1998: p. 286). While this view was already mistaken a decade ago, it appears even less plausible today, as I shall demonstrate in the remainder of this article.

Explaining Immigration Policies

A state's decision to admit immigrants, without which there is either no immigration or at best (or worst) 'illegal' immigration, is formally a function of its sovereignty, as codified in international law, according to which states are free to reject or to expel noncitizens (within due process constraints). This

linkage between immigration policy and sovereignty is expressed in the standard notion, propagated by governments around the world that immigration policy is in the 'national interest.' The problem is that, particularly in liberal states, the 'national interest' is no fixed thing, standing above group interests and notoriously short of organizational manifestation. In a pathbreaking essay, which continues to be the single most influential political science treatise on immigration policy, Gary Freeman (1995) explained in rational-choice terms why 'special' instead of 'national' interests shape the immigration policies of liberal states. According to Freeman, the costs of immigration are diffusely spread over the population, while its benefits are concentrated (for employers and co-ethnics). It follows from the logic of collective action that the beneficiaries of concentrated benefits win over the bearers of diffuse costs, in a constellation that Freeman calls (following J.Q. Wilson, 1980) 'client politics.' This simple model explains the paradox that liberal states, despite their restriction-minded elite rhetoric and public opinion, have remained largely open to (certain kinds) of immigrants.

A number of authors have quickly picked up and revised or amended Freeman's model. In a cogent political science analysis, Jeannette Money (1999) has argued that because of the spatial concentration of immigrant settlement also the costs of immigration are concentrated, thus remedying the free-rider problem in these geographic areas and giving rise to a constellation that Wilson (1980) had called 'interest-group politics.' The restrictionist impulse, first picked up by local politicians, can go nationwide if the respective district is crucial for maintaining or gaining a national electoral majority. Demonstrating this swing-vote dynamics in the cases of France, Great Britain, and Australia, Money's revision of Freeman's model helps explain why some states remain open to new immigration, while in others immigration control is put on the national political agenda. Joppke (1998b, 1999) has argued that the logic of client politics is more firmly established in classic immigrant nations than in European states, where pro-immigrant lobbies are much weaker, and where nominal 'zero-immigration policies' fit more easily with 'national interest' rhetoric. In addition, he stressed (much like Hollifield, 1992) that liberal norms, which invest immigrants with rights, are a second constraint on state policy, next to interest-group pressure. Reference to liberal norms, backed by independent courts, helps explain why European states, despite the absence of an ethnic lobby there, have remained open to certain kinds of immigrants, most notably the family members of labor migrants. Once the role of judicial constraints and 'self-limited sovereignty' of the constitutional state (Joppke, 1998b) was on the map, the next round was to qualify that. Discussing the case of Japan, Amy Gurowitz (1999) argued that in a non-Western state, the liberal-constitutional infrastructure is much weaker, so immigrant activists resort to global human rights norms and regimes (that Joppke (1998b) had found less important than domestic-level legal norms and actors). Comparing guest-worker policies in Switzerland and Germany, Antje Ellermann (2013) even argued that political factors are more important than legal factors to explain the success or failure of these policies. Switzerland, where there is no constitutional court watching over the executive, managed to carry through the 'rotation' of guest workers because of past (negative) policy-learning and the lacking insulation of an (liberal-leaning) executive from populist pressures (due to its direct democracy); Switzerland is the case of a liberal state *not* having to accept 'unwanted' immigration. By contrast, West Germany saw guestworker migration turn into permanent settlement because of the nonpossibility of policy-learning (due to the state collapse in 1945) and 'rotation' kicking in as policy objective too late in time, in a context of greater executive state insulation from popular and business pressure, and after settlement had already occurred. In sum, not legally based 'self-limited sovereignty' but the institutional setup of the recruitment systems and more narrowly political factors matter for understanding the fate of guestworker policies. Also note that, in the 1990s, Germany devised a second-generation guest-worker policy, this time with Poland, that strictly enforced the temporariness of this migration from the start so that these 'guests' would not stay (see Castles, 2006).

When linking the analysis of immigration policy to the larger question of the resilience or transformation of sovereignty in an era of globalization (competing views on this are laid out in Joppke (1998a); also Guiraudon and Lahav, 2000), one must strictly distinguish formal state authority from empirical state capacity. As conceptualized in international relations theory and implemented under international law, 'sovereignty' refers to the formal last-instance authority of the state within 'its' territory. In this formal sense, even ineffective immigration controls say nothing about the presence or absence of state sovereignty over immigration. Instead, the crucial test is if actors other than the state have acquired formal last-instance authority over immigration matters. With some important exceptions, such as the free movement regime within the European Union (which is mostly not emulated by other regional regimes), this test will almost always be negative. One must even register that the constitutive quality of the state to be a container of people has greatly increased in the current era of globalization, where the state has been in retreat on so many other fronts. An altogether different question is whether the presence of unwanted migrants within their territories (such as illegal migrants or asylum seekers) signals a declining empirical capacity (as against formal authority) of states to control immigration. The effectiveness of Western states to bring down, first, the number of unwanted asylum seekers in the 1990s through a combination of national-level and supranational (EU-level) restrictions, and, second, to impose new restrictions on family migration once the 'action' had shifted to that front a decade later, but, above all, thirdly, to digitally control borders and territories with new technologies suggests that there is little evidence for a decline of empirical state capacity (see Guiraudon and Joppke, 2001; Mau et al., 2012).

But 'state capacity' is no static thing. As Antje Ellermann (2009) showed in an important study of deportation policies in Germany and the United States, the state capacity to deport immigrants varies not only across countries but, above all, according to the phase of the policy cycle. Accordingly, law-making on deportation is facilitated by institutional linkages with the (generally restriction-minded) public, while implementation is more effective when bureaucrats are insulated from the public gaze, which now works in favor of

the attention- and sympathy-catching victim of this most brutal form of 'social regulation.'

Two new developments in immigration policy in the past decade have been, firstly, the selective opening of developed European and East Asian states to high-skilled immigration, which went along with a narrowing of previous differences between classic immigration countries and the various newcomers (or rather latecomers) in the developed world; and, secondly, the growing pressure for building an international (or 'global') regime for managing migration, which, however, tends to be permanently frustrated. With respect to the first, after the liberal delegitimation of selecting immigrants by their ethnic or racial origins (see Joppke, 2005), the only selectivity left for states is on the grounds of migrants' skill profile. While there is dramatic demographic (and sometimes economic) need for large numbers of low-skilled immigrants, particularly in Europe and East Asia, no democratically accountable government dares acknowledging this need, for populist reasons. In almost all states of the world, low-skilled immigration, if admitted at all, is strictly limited to seasonal, nonpermanent migration (the most recent craze being about policies that may allow 'circular' migration). With respect to high-skilled immigration, the story is dramatically different. No developed state in the world, not even the notorious 'no-immigration countries' Germany and Japan, dares abstaining from the 'race for talent' (Shachar, 2006) that marks the contemporary global economy (for Japan, see Skrentny et al., 2012). Germany, since its new immigration law of 2004, grants instant permanent legal residence permits for high-skilled immigrants, thus radically departing from the old European logic of only gradually increasing residence rights (*Aufenthaltsverfestigung*) (but it keeps this inflow small through asking for a job offer at hand and high-income requirements).

The new turn to high-skilled immigration directs attention to the different possibilities that states have to steer this migration (see Sachverständigenrat, 2013: pp. 16–24). First, there is the possibility of employer-centered selection, whereby a prior work contract is required for admission. The model for this is the American H1B visa, which has channeled America's need for high-skilled immigrants within an immigration system that heavily prioritizes family migration. Interestingly, Germany has followed the American H1B model in its recent opening to high-skilled immigration, especially in the IT sector. A second, though less utilized, possibility is sector-specific programs, where labor-scarce sectors or professions are provided with quota that may be filled by immigrants even without a prior work contract. Thirdly, the so-called points systems of Canada or Australia prize human capital irrespective of concrete labor market needs, only requiring immigrants to pass a numerical threshold of a scale rewarding youth, education, and language abilities. In reality, however, one can observe the emergence of 'hybrid' systems of recruiting high-skilled immigrants, which greatly reduces the previous variety of national approaches (see Papademetriou and Sumption, 2011). Canada, for instance, increasingly issues only temporary visa, even for high-skilled immigrants, who only gradually may 'earn' the right to permanence, European-style, and it layered onto its points system a prior 'scarce profession' proviso or the requirement of a job offer at hand, which integrates elements of employer- and sector-driven immigrant selection. Conversely, Germany, in terms of a recently reformed Paragraph 18 of its Residence Law, now allows non-EU academics to enter Germany in search of a job, thus obliterating the prior requirement of a formal job offer (for a similar comparison of Spain and Canada, see Finotelli (2012)). The reality of immigrant selection is highly complex and in flux, defying stereotyped national models or old types of immigration or nonimmigration country, and academic accounts are often outdated before they go into print.

A second recent trend has been pressure for building an international regime for managing migration such as the UN-sponsored Global Forum on Migration and Development. Parallel to this, academics have mapped the few elements pointing toward an international regime, normatively stipulating the need for one that is far more elaborate than at present (see Betts, 2011). Simple interest arithmetic shows why no international regime exists or is likely to come into existence anytime soon. The main problem is fundamental interest 'asymmetry' with respect to low- and high-skilled immigrants in sending and receiving countries (Bhagwati, 2004). With respect to low-skilled migration, supply greatly exceeds demand, and there are few incentives on the part of underdeveloped sending states to restrict these moves (the only exception being bilateral agreements that may exchange restricted emigration against development aids). With respect to high-skilled migration, the opposite constellation prevails, the demand for this migration greatly exceeding supply, with sending countries showing little motivation to condone massive brain drain. No international regime is ever to emerge in this totally divergent interest constellation.

Integration and Citizenship

A second line of new and innovative scholarship on the politics of immigration has opened up over the impact of immigration on states as 'membership associations' (Brubaker, 1992). A variety of authors have concluded from the upgrading of immigrant rights across liberal states that 'citizenship' as unitary membership form and focus of collective identity in modern states has been devalued and set on a path of decline, with a dissociation between 'postnational membership,' protected by a global human rights regime, and parochial or larger-than-national identities (Soysal, 1994). At the same time, migrants' 'transnational' practices and 'diasporic' forms of association are said to increasingly bypass the nation-state, thus rendering irrelevant old models of one-directional integration and assimilation (e.g., Glick Schiller et al., 1992).

Two decades later, it is obvious that 'postnational' and 'transnational' approaches have underestimated the resilience and adaptability of the national citizenship construct (for an overview of recent trends, see Joppke, 2010a). The vulnerabilities of noncitizens became clear, first, in the US mid-1990s' welfare reforms that restricted federal social benefits for legal immigrants, and, post-2001, in antiterror laws that primarily targeted noncitizens. In Europe, immigration has triggered not a decline but a transformation of citizenship. The

continent that two centuries ago had been a pacesetter of the postfeudal, 'modern' principle of family- and descent-based citizenship (jus sanguinis) has undergone a reverse trend toward territorial citizenship (jus soli), originally a feudal principle that had been found wanting in the dawning era of nation-states. By the 1990s, most member states of the European Union granted second- and third-generation immigrants a right to citizenship either at birth or at majority age, old assimilation requirements for naturalization were waived, and there was increasing pragmatic acceptance of dual citizenship. Interestingly, new restrictions after the terrorist attacks of 2001 only entailed a tightening of naturalization rules, by means of citizenship tests and new civic integration requirements, while the trends toward jus soli citizenship and the toleration of dual citizenship were not reversed.

As citizenship obviously continued to be the lodestar of immigrant integration, a new literature inquired into the determinants of liberalizing or restricting the access to it. In a 25-country comparison, Patrick Weil (2001) argued that three factors had to be in place for a liberal opening of citizenship: a liberal-democratic legacy; noncataclysmic, past immigration that is accepted as irreversible; and a congruence of national and state boundaries. While a parsimonious model that hardly meets a case that does not fit, it is also functionalist and ex-post, saying little about the political dynamics underlying the evolution of citizenship. Joppke (2003) argued that this evolution was actually in two opposite directions, conditioned by party politics, a 'de-ethnicizing' direction under left-wing governments (facilitating access to citizenship for immigrants), but a 're-ethnicizing' direction under right-wing governments (strengthening ties with emigrants and expatriates abroad) (see also Janoski (2010), confirming the de-ethnicizing trend under left-wing governments). In a compelling comparison of post-Enlargement EU states, Marc Morjé Howard (2009) found the left-right hypothesis wanting. What instead explains liberal reform is the absence of mobilizing a latent anti-immigrant disposition among mass publics, while the presence of such mobilization, often instigated by far-right parties, may lead to new restrictions, even under left-wing governments.

If one considers the traditional closure of ethnic nation-state citizenship to immigrants (for which there had been a complement in the Americas in terms of racial exclusion), the de-ethnicization of citizenship, particularly in Europe, is clearly the more astonishing trend. It went along with an intransitive mode of immigrant integration across liberal states. According to this intransitive mode, immigrants are not the object of forced assimilation, as in the 'Americanization' campaign in the early twentieth century, but are the subjects of freely willed integration. In the process, 'integration' tends to be favored over 'assimilation,' if the latter is not shunned altogether (particularly in Europe). Against a backdrop of weakened nationalist semantics post-World War II, it means that immigrants are expected to adhere to the procedural values that constitute liberal-democratic states; they are not expected to become 'assimilated,' that is to take on the substantive life forms of a particular nation-state. Assimilation may well be the popular expectation, but it just cannot be enforced by means of public policy that is constrained by liberal-democratic norms. In this minimal sense, which could not be derailed by the new wave of citizenship tests and civic integration requirements since the early millennium (see Joppke, 2007; Bauböck and Joppke, 2010), Nathan Glazer's (1997) pronouncement that "we are all multiculturalists now" remains valid. The fundamental change of attitude is visible, for instance, in Germany's move away from individually tested cultural assimilation (*Hinwendung zu Deutschland*) in liberalized naturalization rules in the early 1990s, which even introduced a right to citizenship under certain conditions. And the reassertion of 'Americanization' in the mid-1990s United States stressed that "ethnic and religious diversity based on personal freedom is compatible with national unity" (US Commission on Immigration Reform, 1997: p. 25).

As carriers of legitimate cultural difference, immigrants cannot but undermine the principle of modern nationhood that Ernest Gellner famously identified in the congruence of political and cultural boundaries (1983). This inevitable *de facto* multiculturalism, however, is to be distinguished from policies of official multiculturalism, which have come under fire almost everywhere (see Joppke, 2004). Multiculturalism's most concise philosophical formulation (Kymlicka, 1995) wisely concedes that immigrants, by voluntarily leaving their society of origin, have 'waived' the right to have their homeland resurrected in the receiving society. The retreat from multiculturalism and turn to 'civic integration' implicitly follows this reasoning, allowing immigrants as individuals to pursue their religious and cultural ways of life, while denying them state support to prosper as groups and instead defining the task of public policy as binding immigrants into mainstream institutions.

Indeed, the most important policy innovation with respect to immigrant integration in the past 15 years has been the rise of 'civic integration' and new citizenship tests. In the most detailed comparative account available today, Sara Wallace Goodman has argued, "the new requirements do not signal departures from national approaches to citizenship, but rather fortify them" (2014). The metaphor of 'fortification' is brought against that of the 'lightening' of citizenship, suggested by Joppke (2010b), who argued that citizenship in liberal states is increasingly 'lite' – that is, easy to access, increasingly less exclusive with respect to rights, and capped by thin, procedural identities that are exchangeable across states. Against this diagnosis, Goodman's main claim is that national variations or 'models' of citizenship and immigrant integration are not overcome by new 'convergent' civic integration policies (as first argued in Joppke, 2007), but that nationally distinct citizenship traditions continue to prosper in the context of 'resilient nation-states' (Goodman, 2014). She thus refutes an entire prong of recent scholarship that has found the old distinction of 'national models' – such as French Republicanism, British multiculturalism, or German-style nonintegration – wanting to understand changing integration and citizenship policies.

Goodman's unquestionable contribution is to show that civic integration is not all of one cloth but differing according to 'scope,' 'sequencing,' 'density,' and – above all – 'purpose' (see Goodman, 2012, 2014). With respect to 'purpose,' she argues that the new policies may be liberal or restrictive,

depending on the two variables of existing citizenship legacies and political conflict surrounding them. Within this frame, Goodman finds much variation across Europe. However, she underrates the degree of *change*, often in departure from existing citizenship traditions, which was brought about by the new civic integration policies. For instance, 'restrictive continuity' (a pattern identified for Austria and Denmark) may be a good description for Austria, but it is not for Denmark, which was once as 'liberal' as its Nordic neighbors and only recently turned into a paragon of restrictiveness, under the pressure of one of Europe's most extreme right-wing parties (the Danish People's Party). Secondly, contrary to her claim, there has been no unambiguous 'liberal continuity' in the UK. Only consider the 'probationary' and 'earned' citizenship schemes proposed in the early millennium by the late Labor government under Tony Blair, which were meant to make citizenship more exclusive, even 'virtuous,' and which were scrapped only last minute, under the new Tory government of David Cameron. In sum, in Britain there seems to be less straightforward continuity in citizenship policy than oscillation between liberal-inclusive and restrictive approaches. Thirdly, qualifying Germany's stance as 'restrictive moderation' belittles the significant departure from its 'ethnic' citizenship legacy in the great citizenship reform of 1999, where Germany introduced conditional jus soli citizenship for the children of settled immigrants, following the European trend. It is a stretch to call the purpose of German-style civic integration (which mostly consists of requiring immigrants to learn German, in order to increase their labor market chances) as 'leaving a restrictive citizenship relatively insulated from change' (Goodman, 2014). In reality, there has been real liberalizing change in 1999, as there had been in a previous reform, that is, the 1992 liberalization of ultrarestrictive naturalization rules. If one further considers the introduction of a distinctly nonmoral, noncultural federal citizenship test in 2008 with a near 100% pass rate, what is Germany's 'national approach to citizenship' that is supposed to be maintained here? Finally, it is problematic to group France and the Netherlands in one category of 'liberal moderation.' The French *contrats d'accueil et d'intégration* are as soft and service oriented as they could be, almost Canadian style. It is implausible to square them with the nastier 'integration from abroad' schemes concocted in the Netherlands, which require immigrants to be familiar with Dutch language and history even before they enter the Netherlands, and which are really an immigration control policy under a different name, aiming to restrict unwanted family migration from Muslim societies.

It is correct to argue that by means of the new civic integration policies, the modern nation-state 'reasserts' its 'community-defining competence' (Goodman, 2014). And it is indeed novel that integration is now 'assessed' through explicit and objective criteria that allow no second guessing, whereas in the past, integration was simply 'inferred' from residence time and left to the individual to fill with meaning (Goodman, 2014). But this is no replication of classic nation-building, and it is certainly exaggerated to claim that the nation-state is 'stronger than ever,' 'a resilient and flourishing entity of political order' (Goodman, 2014). This is an odd picture for Europe, where European Community law has bitten significant holes into the possibility of exclusive nation-state citizenship (see Joppke, 2010b). If one examines instead the contents of civic integration requirements and their cognitive and normative dimensions (largely ignored by Goodman), one discovers a reality of *changing* state identities today. A comparison of four West European countries and the United States found that the civic knowledge expected of new immigrants and citizenship applicants is mostly procedural and related to the principles of liberal democracy, thus remaining within the confines of 'political liberalism' à la John Rawls (Michalowski, 2011). Civic integration is no return to cultural assimilation. It has more in common with a general turn of social policy from welfare to workfare (see Gilbert, 2002), in seeking to make immigrants (much like the nonimmigrant rest) functioning participants in society's productive core activities, especially the labor market – note that one of the strange peculiarities of Europe, unknown in America or Australia, is that immigrants are at a minimum double as likely to be unemployed as natives (see Hansen, 2012). This is not to deny that there are repressive possibilities under the mantle of liberalism, in terms of scrutinizing people for their 'loyalty' and personal identification with liberal-democratic principles, which amounts to liberalism hyped up as identity. However, 'repressive liberalism' raises eyebrows precisely for the strange 'repressive–liberal' pairing, examples for which remain rare (see Joppke, 2010a: pp. 137–142). If one scrutinizes the 'new parameters of belonging under the banner of liberalism' (Goodman, 2014), one discovers a reality not different from the one arrived at from the vantage point of 'lightened' citizenship, only that the latter has the advantage of factoring in more explicitly the uses of liberalism in reformed citizenship schemes (Joppke, 2010a: Chapter 4).

Abstract

This article introduces a social psychological perspective for understanding phenomena related to immigration in culturally diverse societies. The viewpoint of both national majorities and immigrants is considered. In the first section, we examine how immigration affects identification processes of national majorities and immigrant minorities, and the consequences of identification for intergroup attitudes. In the second section, the role of threat perceptions, stereotypes, and worldviews in national majorities' stances toward immigrants is presented. Moreover, the psychological consequences of discrimination for immigrants are overviewed. In the final section, both intergroup contact between the national majority and immigrants and multicultural norms are discussed.

Throughout the history of humankind, people have migrated. In more recent history, people have left their countries of origin voluntarily or involuntarily for different reasons varying from colonialism, war, political persecution, economic scarcity, family reunification, and to search for new and better life experiences. The numbers of individuals immigrating increase every year: From 2000 to 2010, the total number of international immigrants increased from an estimated 150 million to 214 million (IOM, 2010). The geography of migration also changes over time. For example, migration takes place not only from the 'South' to the 'North,' but also more and more within African, Asian, and Latin American regions. Moreover, former emigrant countries in Europe have become receiving countries during the twentieth century.

While migration benefits the world economy and is an important source of income for developing countries, it also poses societal challenges ranging from human trafficking, 'irregular migration' due to restrictions in immigration laws to marginalization of immigrant communities. Indeed, immigrants are often confronted with negative or even hostile reactions from the national majority of the receiving country (i.e., the citizens with no foreign roots). Frequently immigration is debated and politicized in the culturally diverse societies of today. For instance, radical and populist right-wing parties rely on negative representations of immigrants (e.g., immigrants abuse the welfare system) to mobilize voters among the national majority.

This article provides a social psychological perspective to immigration, presenting insights both on national majorities and immigrant minorities. It should be kept in mind however that the distinction between immigrant and ethnic groups is not always clear-cut. Individuals may be born in a given country but have foreign roots. They may also have mixed cultural and ethnic heritage. Finally, despite the fact that indigenous and aboriginal populations are not immigrant minorities, they also often face strong discrimination. Thus, social psychological research on immigration overlaps to some degree with research on national and ethnic minorities.

The article is divided into three sections. First, we discuss how immigration affects identification processes of national majorities and immigrant minorities, and the consequences of identification for intergroup attitudes. Second, we examine the role of threat perceptions, stereotypes, and worldviews in national majorities' stances toward immigrants, and the psychological costs and consequences of discrimination for immigrants. Finally, we discuss the role of intergroup contact between the national majority and immigrants, and of policies and norms in facilitating or hampering harmonious coexistence in culturally diverse societies.

Identification: Defining the In-Group and Relations to Out-Groups

When immigrants settle in a receiving country, both the national majority and immigrants as newcomers create and negotiate boundaries between their in-group and the out-group. This is reflected in in-group identification as well as in attitudes toward members of the other group ranging from tolerant to hostile, and from straightforward to ambivalent. But identities and group boundaries resulting from immigration are not set in stone: They fluctuate over time and as a function of group and individual status.

How the National Majority Defines Itself

Compared to immigrants, national majorities have typically paid less attention to their ethnicity and nationality. However, the increasingly diversified composition of receiving societies has rendered majorities' own ethnic and national background visible, and made them aware of group boundaries. The way majority members define belongingness to the national in-group is a way to evaluate how they react to ethnic diversity. These definitions of nationhood are generally divided into two categories (Smith, 1991). An *ethnic definition*, based on supposed shared ancestry, traditions, and culture, implies an impermeable understanding of the nation: Individuals endorsing this vision believe that immigrants cannot become 'true' members of their receiving country. This may not even be a conscious thought. For instance, white Americans, and to some extent members of ethnic minorities, implicitly and automatically associate being American with being white,

a characteristic that nonwhite individuals can hardly acquire (Devos and Banaji, 2005). Based on the notion of citizenship, a *civic definition* of nationhood implies more permeable group boundaries than the ethnic definition. For example, by learning the local language or acquiring citizenship, immigrants can be accepted as full members of the national in-group.

The way members of national majorities define the national in-group's boundaries is closely related to the nature of their attachment to the nation. Those endorsing an ethnic definition generally express a blind and uncritical allegiance to the nation, perceived as superior to other countries. This form of national attachment – nationalism – frequently underlies negative reactions toward immigrants. Those with a civic vision of the nation, in turn, tend to express a more critical attachment to the nation. This form of attachment – patriotism – involves being proud of the nation's democratic institutions and values, and monitoring whether democracy is actually enacted. Finally, although a civic vision implies a perception of the nation's boundaries as more permeable than an ethnic vision, it nevertheless entails restricting access to the national in-group.

Identities among Immigrant Minorities

Ethnic identity is defined as a sense of belonging based on one's ancestry, cultural heritage, values, traditions, rituals, and often language and religion. Ethnic identity is thus composed of more or less connected facets that can vary across immigrant groups and across situations. For instance, religion may play a more central role in defining identity in some immigrant groups, as it has been found for Muslim immigrants in various countries. Another important distinction has to be made between national and ethnic identity, since for immigrants coming from multiethnic nations, and especially when there are tensions between the different ethnic groups, being attached to this nation holds a different meaning than being attached to one's own ethnic group (Deaux, 2006).

Beyond their relation to the (ethnic, religious, and national) in-group, immigrants also form bonds with the receiving country. The intersection of the desires to maintain the culture of origin and to have contact with members of the receiving country (Berry et al., 2006) or to adopt its culture (Bourhis et al., 1997) forms four *acculturation* strategies. *Separation* occurs when immigrants want to maintain their culture and avoid contacts with the receiving country. On the contrary, *assimilation* implies renouncing the culture of origin and embracing the one of the receiving country. *Integration* denotes the strategy of immigrants who want and do both, while *marginalization* implies that immigrants adopt neither. Refining the notion of marginalization, Bourhis et al. (1997) distinguish *individualism* – immigrants' own decision not to identify with a group because they see themselves as individuals above all – from *cultural alienation* – when immigrants, for various reasons, cannot identify with any group. Integration has been shown to be most beneficial for the psychological well-being of immigrants (e.g., less stress, less anxiety, higher self-esteem).

The adoption of an acculturation strategy is not only guided by one's desires, but also by external factors. Indeed, real or perceived expectations of the receiving society reflected in immigration policies, the history of immigration, the interactions with members of the national majority, as well as the degree of similarity (e.g., in language, culture, or ethnicity) between their country or culture of origin and the receiving country influence immigrants' strategies (Brown and Zagefka, 2011; see Section Policies and Norms in Culturally Diverse Societies). Finally, a distinction between different domains of acculturation is necessary for understanding immigrants' acculturation strategies in the receiving country. For instance, immigrants may favor assimilation in the professional and public sphere but prefer separation for more private matters such as family and religious beliefs.

Beyond an Immigrant vs Receiving Country Citizen Dichotomy

The increasingly diversified flows of immigrants and the long history of migration in many receiving countries have multiplied the landscape of possible identities, creating complex feelings of belonging that cannot be captured by a mere immigrant vs nonimmigrant dichotomy. More and more individuals with an immigrant background are born in the receiving country (the so-called second or third generations) or immigrate at a very young age with their parents (the so-called 1.5 generation). Children and adolescents often acculturate at a faster pace than their parents. As parents are generally keen to transmit the values and culture of the country of origin, differences in acculturation strategies and pace of acculturation may engender intergenerational conflicts within families.

Moreover, individuals with an immigrant background are described as bicultural when more than one cultural mind-set informs and influences their behavior (Hong et al., 2000). Bicultural individuals, and especially those who perceive their two cultures as compatible, interpret the same event differently as a function of the mind-set that is salient at a given moment. For example, Chinese students in the US have been shown to attribute more internal causes (e.g., personal agency) to an event when guided by a Western, individualistic mind-set, and more external and group-related causes when guided by an Eastern, collectivistic mind-set.

Intergroup Conflicts in the Context of Immigration

The arrival and settling of immigrants can give rise to conflicts and resentment between immigrants and members of the receiving society. In the media, in political discourse, and in everyday conversations, immigrants are often portrayed as a threat to the receiving society and its members. Such threats provide a fertile ground for the national majority to express hostility toward immigrants, and legitimize their exclusion from economic, social, and political life (e.g., Wagner et al., 2010). Immigrants on the other hand, face the challenge of finding their place in the receiving society, for example, due to discrimination at school or the workplace. Immigrants therefore develop strategies to overcome these difficulties and voice their claims.

Intergroup Conflict from a Majority Perspective

A perception that immigrants threaten the national majority is often at the origin of negative stereotypes and anti-immigrant prejudice. Such threats can be grouped into two major

categories: realistic threats and symbolic threats (Riek et al., 2006). Realistic threats concern immigrants competing with the majority for tangible resources such as jobs and housing. As immigrants frequently have a lower socioeconomic status and more unstable job prospects than the national majority, they can be seen as a potential financial burden by taking advantage of welfare benefits. Initiatives to acquire rights and to participate in decision making (e.g., by claiming voting rights) may also be perceived as a threat, namely to the existing power arrangements privileging the national majority. The underlying assumption is that whenever groups compete for limited resources, they develop hostile attitudes toward each other. The resources are thereby viewed as a zero-sum, that is, the gain of immigrants inevitably implies a loss for the majority (Esses et al., 1998). Perceived *similarity*, such as equal educational qualifications, between immigrants and the national majority on the job market can fuel perceived realistic threat (Zárate et al., 2004). This is one explanation why opposition to immigration is generally greater among members of the national majority with a low socioeconomic status. Symbolic threats, in turn, refer to the perception that immigrants undermine the values, customs, and traditions of the majority. These threats refer to *differences* between immigrants and the majority, especially when values and beliefs are perceived as incompatible with each other. Those perceiving different cultures as irreconcilable generally express a greater opposition to the incorporation of immigrants into the national in-group (e.g., by opposing lenient citizenship policies), because they may fear that the founding features of the national in-group (e.g., its religion) will lose their distinctiveness. In addition, they often oppose immigrants' attempts to maintain their cultural and religious practices.

Immigrant groups trigger different reactions in majority members. While overall stereotypes of immigrants are negative, stereotypes of specific immigrant groups are more nuanced, and often ambivalent (Lee and Fiske, 2006). The perceived status of immigrants and their country of origin determine emotional reactions toward them. In the US, for instance, while high-status immigrants (such as Asian immigrants) tend to elicit envy or admiration, low-status immigrants (such as undocumented immigrants) tend to elicit pity or contempt. Whether immigrant groups are valued or not also influences the relations that majority members wish to entertain with them. While immigrants from 'valued' (e.g., wealthy and perceived as culturally close) countries are often invited to integrate into the receiving society, immigrants from 'devalued' (e.g., poor and perceived as culturally distant) countries are more frequently expected to assimilate, or are even excluded (Montreuil and Bourhis, 2001; see also Sections Identities among Immigrant Minorities; Policies and Norms in Culturally Diverse Societies). With growing international mobility, the cultural and religious diversity of immigrant groups has increased in many countries. Policies that explicitly attract some immigrant groups while denying entry or family reunification to others are likely to further encourage double standards in attitudes toward immigrants. In addition, the perceived status of immigrants can change over time. Recently arrived immigrants are more likely to be targets of prejudice than older immigrant groups, which are gradually seen as part of the national in-group. Indeed, with increasing attachment to the receiving country and competition for resources, longer established immigrant groups may develop exclusionary attitudes toward more recent immigrant groups.

Moreover, individual differences in worldviews influence majority members' attitudes toward immigrants. Especially individuals who value coercive social control, obedience to authorities, and conformity to norms easily feel threatened by immigrants (Right Wing Authoritarianism, RWA, Altemeyer, 1988). Their attitudes toward immigrants fit their view of the world as dangerous and threatening, where social cohesion, moral values, and collective security are easily undermined by deviants and outsiders. Moreover, individuals who prefer hierarchical rather than egalitarian relations between groups (high on Social Dominance Orientation, SDO; Pratto et al., 1994) often express negative attitudes toward immigrants. Such individuals tend to view the world as ruthlessly competitive, and are quick to judge immigrants as competing with the national majority for limited resources, status, and power. Given their different values and concerns, individuals high on RWA or SDO are sensitive to different characteristics associated with immigrants: Due to their focus on conformity, individuals with RWA tendencies will be threatened by immigrants perceived as different from the majority or unwilling to assimilate. Individuals with high SDO tendencies, in turn, will feel threatened by immigrants perceived as too similar to the national majority, because of the potential decrease in status asymmetry between immigrants and the national majority.

The wider socioeconomic context also shapes individuals' attitudes toward immigrants (e.g., Green and Staerklé, 2013). Indeed, intergroup competition and threat thrive in deprived economic conditions (e.g., high unemployment). Though a high proportion of immigrants (e.g., in a neighborhood or in a region) may increase threat (see however Section Improving Intergroup Relations with Intergroup Contact), the *perception* of a strong immigrant presence is sufficient to trigger threat. Threat is also actively fueled by social and political narratives in the media and political debates, which frequently have a greater influence on attitudes toward immigrants than the actual presence of immigrants (Wagner et al., 2010).

Intergroup Conflict from a Minority Perspective

When settling into a new country, immigrants come across a number of challenges. These challenges can be practical, such as finding a job or learning the language, or involve a legal or political dimension, such as securing residency and achieving political rights. Discrimination by the national majority, including unfair treatment, restricted opportunities, and disrespectful and hostile behavior, creates or strongly contributes to these challenges. Discrimination can be directly experienced in interactions with the majority, or it can be institutionalized and reflected in policies. Experiences of discrimination have severe consequences for the lives of immigrants. They cause psychological symptoms such as distress, low self-esteem, anxiety, and depression. The resulting general and chronic health issues may then hamper immigrants' integration and performance on the job market. Such health issues can be amplified by the segregation of immigrants in poor and unsafe neighborhoods offering restricted health care access. Discrimination is not always direct, however.

The mere awareness of the negative stereotypes that the majority holds of immigrants can render them self-fulfilling prophecies. For instance, stereotype threat – the awareness of others' stereotypes influencing the evaluation of one's performance – also affects immigrants. In the US, second-generation West Indian immigrants, when identifying with black Americans, underperformed at school when they believed academic ability to be measured (Deaux, 2006). Similarly, in the UK, young black men adopted gang-style behaviors generally attributed to their group by the white majority (Howarth et al., 2013). These examples show how majorities' representations of ethnic and immigrant groups – also known by the groups themselves – are likely to maintain and intensify the status gap between immigrants and the majority.

Immigrants can counteract negative stereotypes and discrimination in different ways. According to the Rejection Identification Model, reinforcing identification with the in-group may help immigrants cope with discrimination (Schmitt and Branscombe, 2002). Indeed, increased identification and strong bonds with the in-group is a source of self-esteem that buffers the consequences of discrimination. Strong bonds with in-group members are also primordial for enabling collective action. Immigrants embedded in ethnic networks, but with social ties to the majority, engage more readily in protest requesting rights and entitlements of immigrants (Klandermans et al., 2008). Experiences of discrimination and feelings of injustice can also lead to less-accepted forms of politicization. For example, British Muslims, who thought that the way British authorities treated Muslims abroad was illegitimate and unjust, were more willing to support both normative (e.g., signing a petition) and nonnormative (e.g., violence against Western troops in Muslim countries) forms of collective action (Tausch et al., 2011).

Living Together in a Diverse Society

In culturally diverse societies, everyday interactions between members of immigrant minorities and national majorities are commonplace. The resulting contacts influence the attitudes of both parties. Moreover, policies and societal norms shape the way in which individuals perceive and think about the relations between immigrants and the national majority. In this section, the notion of *multiculturalism* has several meanings (Berry and Sam, 2013). Multiculturalism implies the presence of cultural diversity. It is also an ideology denoting the willingness of the national majority to maintain and promote cultural diversity and to have contact with immigrants. Finally, multiculturalism also refers to a public policy response to cultural diversity.

Improving Intergroup Relations with Intergroup Contact

Positive intergroup contact has been considered one of the most effective ways of reducing prejudice, especially among majority group members. In the context of immigration this implies that anti-immigrant prejudice of national majority members reduces when they have positive interactions with immigrants. The classic intergroup contact hypothesis states that the optimal conditions for reducing prejudice in an intergroup contact situation include equal status between the groups, common goals, cooperation in achieving these goals, and a supportive institutional climate, for example, in the form of integration policies (Allport, 1954). When immigrants have similar social status to the national majority, reaching these conditions is more plausible. However, as immigrants are frequently at the bottom of the societal hierarchy in the receiving countries, equal status and common goals (due to different needs and interests) are rarely reached in a relationship between a national majority member and an immigrant. Nevertheless, there is now extensive evidence that contact improves attitudes toward immigrants even when these optimal conditions are not fulfilled (Pettigrew and Tropp, 2006).

To have practical value, it is crucial that the impact of positive contact generalizes beyond a specific contact experience to new situations, to the entire immigrant group, and even to other immigrant groups. Three different models explain how contact generalizes to positive attitudes toward immigrants (for overviews Brown and Hewstone, 2005; Hewstone and Swart, 2011). First, positive interpersonal interactions between an immigrant and a national majority member can render salient the *personal* characteristics of the immigrant, instead of category membership. Immigrants are seen as distinct individuals, rather than as a homogenous group, thereby blurring the boundaries between the two categories. Such *decategorization* can result in more positive attitudes toward immigrants. Second, contact can also lead to redrawing of group boundaries, or *recategorization*, where immigrants and members of the receiving society are associated with the shared superordinate group (e.g., 'we are all Europeans'). Embracing this common in-group identity then reduces prejudice. A third model suggests, in turn, that the *distinction* between immigrants and the majority should be *salient*: It is necessary to conceive the situation as *intergroup* contact for the effects of positive contact to generalize to the immigrant out-group as a whole. These models can be considered complementary insofar as contact requires both interpersonal and intergroup significance for positive immigrant attitudes to generalize beyond the contact situation.

How does contact reduce anti-immigrant prejudice? Different social psychological processes (mediational mechanisms) have been put forward (Brown and Hewstone, 2005). First, contact enables one to learn about the life of immigrants, and this *new knowledge* then reduces prejudice. Second, agreeable interactions between immigrants and the receiving society majority *increase positive* and *decrease negative effect* toward immigrants. Typically positive contact with immigrants reduces intergroup threat and anxiety. Close contact, and in particular friendships, also allows taking the perspective of immigrants and empathizing with their concerns, which then improves intergroup attitudes. Finally, *self-disclosure* (revealing important aspects of oneself to another person) contributes to the development of interpersonal relationships. Interactions between an immigrant and a national majority member involving self-disclosure thus further improve intergroup attitudes.

Even indirect or distal contact with immigrants reduces anti-immigrant prejudice. First, simply knowing that fellow in-group members befriend immigrants can improve attitudes

toward immigrants even in the absence of direct personal contact. Observing such friendships, in other words experiencing *extended contact*, conveys tolerant in-group norms regarding intergroup relations and increases empathy toward and knowledge about immigrants, which then ameliorate attitudes toward immigrants. Second, contact reduces prejudice against immigrant groups that were not directly involved in the initial interaction. This phenomenon, labeled a *secondary transfer effect*, implies improved attitudes toward one immigrant group that results from positive contact with members of another immigrant group. Third, merely *imagining positive intergroup interactions* has the potential for improving immigration attitudes. Finally, living in culturally diverse societal contexts (depicted with demographic indices such as a high proportion of immigrants in the whole population) provides more contact opportunities. Such opportunities can give rise to positive intergroup contact, for example, through friendships, which then decrease perceived threat and antagonistic attitudes toward immigration (however, for an opposite prediction of the link between proportion of immigrants and increased feelings of threat, see Section Intergroup Conflict from a Majority Perspective).

Intergroup contact also has downsides and can even be counterproductive for improving the situation of immigrants. Positive, more profound interactions indeed reduce threat perceptions and anti-immigrant prejudice. However, superficial, everyday contacts are more frequent (Dixon et al., 2005) than positive, more profound contacts. Superficial contact, especially when it is negative, may consolidate and even heighten anti-immigrant prejudice. The prejudice-increasing effect of negative contact is frequently greater than the prejudice-reducing effect of positive contact. This means that negative experiences (e.g., hostile interactions in the street) with and negative impressions of immigrants have more impact on increasing prejudiced attitudes than pleasant encounters and positive impressions have decreasing them. Also one cannot assume that cultural diversity and actual contact go hand in hand. Indeed, ethnic and immigrant minorities may be informally segregated, and they may even voluntarily do so themselves. For example, actual contact is minimized if immigrants use public space differently to the national majority (e.g., sitting arrangements in classrooms, use of leisure areas). These factors may explain the persistence of prejudice in culturally diverse communities.

Although classical intergroup contact research has advanced the understanding of the processes involved in prejudice reduction, more recent research examines how the way immigrant and minority groups interpret intergroup contact affects strategies for seeking social change and recognition. Positive attitudes toward the national majority can conflict with the interests of immigrants. Pleasant intergroup interactions can actually reinforce the unequal status relations between immigrants and national majorities by disempowering immigrants and thus efforts to realize social change. Positive *interpersonal* contact attracts attention away from perceptions of *intergroup* inequality between disadvantaged immigrants and privileged national majorities, thereby reducing collective action as well as support for policies aimed at combating inequalities and increasing emancipation (e.g., Wright and Baray, 2012 for this phenomenon). Thus, the reduction of prejudice should not be the sole aim in culturally diverse societies. In turn, collective action opposing societal inequality and reducing power differences among immigrant minorities and the national majority should be encouraged.

Policies and Norms in Culturally Diverse Societies

Countries differ in the way they deal with diversity, recognition of immigrant minorities, and their incorporation in society. Multicultural and assimilationist integration policies, and the underlying ideologies, are frequently differentiated. Multicultural policies have two principal goals (e.g., Berry and Sam, 2013): On the one hand, they involve supporting the maintenance of immigrants' culture and tradition and on the other hand, they focus on promoting the inclusion and participation of immigrants in society thereby reducing discrimination, increasing equality, and improving the economic and societal position of immigrants. This is the case in Canada, where multicultural policies have included both the recognition of cultural diversity and the equity and inclusion of immigrants and ethnic minorities. In contrast, in the US and UK policies have mainly focused on the recognition of diversity. Assimilation policies, in turn, are based on the idea that immigrants should adopt the language, customs, and values of the national majorities, and abandon their own cultural heritage. Assimilationist policies thus aim to homogenize the population and to reduce cultural diversity. France has been described as an assimilationist country that expects immigrants to adopt French culture. For example, the controversial law banning visible religious symbols such as the headscarf at school can be interpreted as an assimilationist expectation. In short, while multicultural policies emphasize appreciating differences between immigrants and the national majority, assimilationist policies focus on de-emphasizing these differences.

Multiculturalism and assimilationism are also social psychological concepts referring to *individuals'* acceptance of cultural diversity and support for policies enabling and promoting cultural diversity (Verkuyten, 2007, for parallels with immigrants' acculturation strategies, see Section Identities among Immigrant Minorities). A multicultural view implies awareness and appreciation of differences between immigrants and the national majority. These views are related to proimmigration attitudes, endorsing supportive integration policies, as well as to efforts to improve the societal status of immigrants. Assimilationist views, in turn, oppose such goals. Frequently, multiculturalism appeals more to immigrants than to the national majority who may prefer assimilationism. But not all aspects of multiculturalism are supported to the same degree nor are they applied to all immigrant groups. There may, for example, be high agreement for promoting equal participation in society, whereas encouragement and the provision of financial aid for cultural maintenance gain less support.

Immigrants and national majorities need to *share* the principles of mutual recognition, because a mismatch in expectations of immigrants and the national majority impedes the attainment of a diverse and harmonious society. The interactive acculturation model (Bourhis et al., 1997) defines the ways intergroup relations play out between immigrants and the

national majority depending on the fit between immigrants' and the majorities' attitudes toward the way diversity is organized in society. A consensual fit between the immigrants' strategies and the receiving country's expectations engenders positive intergroup outcomes (see Section Identities among Immigrant Minorities; Brown and Zagefka, 2011). In contrast, a marked mismatch increases negative and conflictual intergroup relations. For example, religious diversity, in particular the role of Islam in Western societies, is currently fiercely debated. Assimilation expectations and the rejection of Muslim values made salient in such debates may threaten Muslim identification, and increase the need to defend and reaffirm one's religion (Verkuyten, 2007). This can then lead to a spiral of mutual disrespect and rejection between the national majority and Muslim immigrants.

Importantly, multicultural and assimiliationist attitudes *develop in individuals' everyday environments* providing normative reference knowledge that guides thinking about immigration (Green and Staerklé, 2013), for example, through the awareness of national policies that condemn or justify anti-immigrant stances. Thus, multicultural or assimiliation policies define the *institutionalized* normative context within a country that orient, in turn, people's attitudes toward immigrants. These policies (such as the multicultural policies in Canada) can influence personal attitudes toward multiculturalism and assimilation. Moreover, a shift toward more inclusive and tolerant integration policies also translates into heightened support for multiculturalism among the national majority. The impact of policies is not necessarily direct. For instance, policies affect perceived norms related to multiculturalism and assimilation, that is, how individuals perceive cultural diversity is dealt with in their country and what is perceived as the expected way to view and treat immigrants (see Guimond et al., 2013). In contrast, by blaming immigrants for societal issues such as unemployment or welfare expenditures, right-wing parties convey an exclusionary normative climate regarding immigration. Such anti-immigrant stances thereby serve important social functions to consolidate and legitimize the position of political leaders and to sustain power relations. Intolerant beliefs widely shared by the national majority also create a climate that fosters anti-immigrant prejudice.

While national policies shape perceived norms on a macro level, the influence of multicultural education takes place on a more proximal level, frequently in a classroom context (see Verkuyten and Thijs, 2013). Indeed, the very objectives of multicultural educational practices are to improve equality between immigrants and the national majority by conveying and establishing antiprejudice norms as well as increasing recognition of existing cultural differences. Learning to accept and recognize cultural differences and prescribing how to treat members of other groups are seen as a route to tolerant attitudes that will help building harmonious intergroup relations. However, despite good intentions, multicultural education is not without pitfalls. Highlighting differences can backfire, for example, if negative stereotypes are reinforced, thereby leading to an increase in prejudiced attitudes. Moreover, sometimes antiprejudice norms are learned superficially without internalization. Only when norms are internalized, that is when individuals personally endorse them, tolerant stances will generalize beyond the classroom.

Imperialism

David A Lake, University of California, San Diego, La Jolla, CA, USA

Abstract

Imperialism is a form of international *hierarchy* in which one political community effectively governs or controls another political community. It is one of the oldest known political institutions, characterizing relations between peoples in ancient Mesopotamia, China, and Rome through modern Europe. It includes rule both within relatively contiguous areas and overseas colonies. Major explanations for imperialism include metrocentric theories, which focus on the internal characteristics of imperial states; pericentric theories, which emphasize conditions within the colonial polities; systemic theories, which highlight competition between the great powers; and relational contracting theories, which explain imperialism by contrast with other possible institutions.

Imperialism

Imperialism is a form of international *hierarchy* in which one political community, or polity, effectively governs or controls another political community. It is one of the oldest known political institutions, characterizing relations between peoples in ancient Mesopotamia, China, and Rome through modern Europe. It includes rule both within relatively contiguous areas – as in the Habsburg and Ottoman empires – and the overseas colonies held by various European states after the Age of Discovery.

The term has a long and tortured history. It was apparently first used as an invective against the expansionist policies of Napoleon I and has been employed most frequently to refer to the colonial practices of the European states in the late nineteenth and early twentieth centuries, attempts to revise the international territorial status quo, and the economic domination of one country by another (also referred to as 'neocolonialism,' see below). Used as a tool of political rhetoric, the term is highly malleable and often devoid of any general meaning.

As an analytic concept, imperialism refers to the effective domination of one political community by another. According to Michael Doyle (1986, 19), "(e)mpires are relationships of political control imposed by some political societies over the effective sovereignty of other political societies …. Imperialism is the process of establishing and maintaining an empire." By domination we mean the ability of the dominant polity – the metropole – to decide policy for the subordinate policy – the colony. This ability may entail substantial delegation of decision-making authority to elite members of the colony, but the metropole retains the power to decide what gets delegated and how, and when this authority is revoked.

Three corollaries are important. First, imperialism occurs only where distinct political communities exist. Subordinate communities may have a prior history of independence, or a new political consciousness may emerge that creates a relationship of imperialism. Without the possession of a distinct political identity, however, class conflict or unequal political opportunities may exist, but not imperialism. The question of what constitutes a distinct political community introduces significant ambiguity about any particular imperial relationship, particularly in previously integrated and territorially contiguous states. Conversely, it is the clarity of the communities that makes imperialism so easily identified with the European overseas empires constructed during the nineteenth century.

Second, the colony lacks an international political 'personality'; that is, while it possesses an identity as a distinct polity, it does not interact with other states as a sovereign equal. Finally, exploitation of the weak by the strong is not inherent in imperialism, but it is an often natural outgrowth of effective domination. The affinity between domination and exploitation explains the often pejorative status of the term.

Imperialism is an extreme form of international hierarchy in which the colony is, in principle, a subject of the dominant state. If imperialism forms one end of a continuum of international hierarchies and 'anarchic' relations between sovereign equals form the other, we can identity a range of increasingly hierarchical relationships, all of which are sometimes called imperialistic. In *spheres of influence*, the subordinate members remain independent but are constrained by dominant powers from forming relationships, such as alliances, with other great powers. Latin America under the *Monroe Doctrine* is a classic example. In *protectorates*, subordinate states yield control over their foreign and defense policies to dominant powers; although subordinates remain independent, they transfer control over specific areas of policy to other states. With continuing responsibility for their defense, the *United States* today retains protectorates over the Federated States of *Micronesia* and the Republic of the *Marshall Islands*. In *informal empires*, subordinates are subject to imperial states across wide ranges of policy but retain their international personalities and interact with third parties on the basis of sovereign equality. *Eastern Europe* under the *Soviet Union* is a particularly clear example. Protectorates and informal empires are often grouped with formal empires as forms of imperialism.

Neocolonialism is a hierarchy produced through the functioning of an impersonal international market. In this variant, the dominant state need not intend to control the subordinate, but the latter is sufficiently dependent upon the former economically that it has little choice other than to comply with (and even anticipate) the metropole's desires. In this case, economic dependence produces political dominance – the core

of imperialism – but the mechanism of control is indirect. For some, this is a virulent form of modern imperialism. For others, the absence of intent negates the political relationship. Neocolonialism remains a contested concept.

Theories of Imperialism

The major explanations for imperialism can be grouped into three general categories. Metrocentric theories focus on the dispositions or internal characteristics of imperial states. Writing in 1902[1965], for instance, John Hobson grounded the motivation for overseas expansion in the necessity for advanced capitalist states to export their surplus capital. This theme was later the foundation for V.I. Lenin's famous monograph, *Imperialism: The Highest Stage of Capitalism*, first published in 1917. *Neo-Marxists* later argued that the *military-industrial complex* and other features of capitalist states actually produced a need for capital, leading states to create colonial and neocolonial relations with developing regions in order to extract wealth (see Magdoff, 1969). Offensive realist theories similarly ground imperialism in the dispositions of great powers and their inherent desires to pursue power over others (Mearsheimer, 2001).

Pericentric theories emphasize conditions within the colonial polities. Where metrocentric theories focus on the push behind expansion, pericentric theories draw attention to the forces that pull imperialists into hierarchical relationships. John Gallagher and Ronald Robinson's *The Imperialism of Free Trade* (1953) set the direction for much research in this tradition. Positing a constant drive for domination and a preference for indirect rule wherever possible, Gallagher and Robinson explained variations in imperialist outcomes by conditions in the periphery. In particular, where peripheral polities possessed stable regimes and effective collaborators, they argued, imperialists could govern indirectly through informal empires. Only where the peripheral societies were unstable politically or lacked elites willing to protect their interests would metropoles be forced to create formal empires and govern directly. As it was effectively ruled by landed interests tied to the British market, in their view, *Argentina* escaped the need for recolonization but was nonetheless caught within Britain's free trade web. Later work on neocolonialism further developed these insights.

Systemic theories of imperialism, typically part of larger defensive *realist* theories of international relations, highlight competition between the great powers (see Cohen, 1973; Waltz, 1979). The struggle for survival and influence between great powers creates an ever-widening gyre of competition, in this perspective, that both leads metropoles to seize territories to augment their resources and allows them to compensate one another using peripheral territories to maintain an effective balance of power. The classic case of imperialism driven by systemic competition was the so-called *Race for Africa* in the late nineteenth century.

The best explanations of imperialism have always combined ideas from more than one of these traditions. Even Hobson, and Gallagher and Robinson, for instance, augmented their theories with a focus on systemic competition, which they both saw as accentuating the metropolitan or peripheral causes of imperialism. More recently, synthetic works integrating all the three approaches have appeared that provide relatively complete explanations of imperialism (see Doyle, 1986; Smith, 1981; Blanken, 2012). Although different authors emphasize different dimensions and different episodes, any single instance of imperialism carries traces of all the three sets of factors. The 'state of the art,' therefore, recognizes and builds upon metrocentric, pericentric, and systemic insights.

A fourth explanation is also being developed that draws upon *neo-institutionalist theory* and especially theories of *relational contracting* as developed in economics. In this approach, imperialism is understood as simply another form of organizational hierarchy. Emphasis is placed on explaining why hierarchy, in general, and this form, in particular, is superior for obtaining the goals of the actors rather than alternative institutions such as *confederations*, protectorates, and state-to-state relations. Three considerations are central. First, the larger the benefits from pooling resources and efforts between the units, in this case the metropole and colony, the more risks or costs the units are willing to accept in building a relationship. Second, the greater the expected costs of *opportunistic* behavior by the subordinate polity, the more important it is to the dominant state to control the actions of its partner. Especially significant here are assets that are specific to the two parties and that would be costly to the metropole if they were withdrawn. In the absence of some *specific assets*, we would expect an 'arm's-length' relationship between independent units, as the benefits of cooperation could then be captured through market exchange. Only where there are substantial assets that are specific to the two parties is imperialism necessary. Finally, there are costs to governing any relationship, and these are likely to escalate with greater hierarchy. Imperialism is typically costly both for the colony, which gives up valued freedom, and for the metropole, which must either bind its own hands to limit its ability to exploit its partner or use coercion to impose its rule. Thus, states avoid empire if control is either unnecessary or can be achieved in some less hierarchical fashion. In this approach, empire is most likely when there are large benefits from pooling resources between the units, highly specific assets at risk, and the costs of governance do not rise sharply with greater hierarchy.

Employing this approach in the case of classic imperialism, Jeffry Frieden (1994) argues that formal empires arose in the age of *plantation agriculture* and *raw materials extraction* as a means of preventing local elites from appropriating site-specific assets in production: once foreign investors opened a copper mine, for instance, this site-specific asset was then subject to expropriation by the local government. Knowing this, foreigners would not invest in such assets without the control made possible by formal empire. As *multinational corporations* have increasingly taken the place of agricultural or raw materials investors, Frieden continues, formal empires have become obsolete. Multinational corporations possess firm-specific assets such as technology or brand names that cannot be easily appropriated by host governments; a government can seize an axle assembly plant, for example, but it is of little value without access to the multinational's worldwide production and marketing network. Thus, formal empire is less necessary to protect corporate assets. David A. Lake (1999, 2009), Alexander Cooley (2005), and others have applied similar arguments to hierarchies motivated by national security

needs. In its emphasis on comparative institutions, this approach brings an additional dimension to the study of empires.

The End of Empire?

Decolonization was one of the most significant events in modern world history. At the dawn of the twentieth century, most of the globe was ruled from Europe. By 1963, the overseas empires had seemingly evaporated. The strong norm against imperialism as affirmed in numerous United Nations declarations strongly suggests that the age of empire is over. Its imprint endures, however. In the periphery, imperial rule destroyed local structures of governance. In some areas, such as *India*, the foundations of parliamentary rule were erected in their place. In other regions, especially Africa, only weak state structures existed when independence arrived, producing political instability and continuing impediments to economic progress (see Jackson, 1990). In the imperial states themselves, political elites underwent a wrenching process of accommodation to their now-diminished international political and economic status (see Kahler, 1984).

Although scholarly interest waned with decolonization, imperialism nonetheless remains a vibrant issue in the contemporary world. Weakly institutionalized groups within *multinational states*, such as the Chechens in *Russia* or the Tibetans in *China*, are pressing demands for independence, declaring in words and actions that the states within which they are embedded are empires. Other groups are rediscovering nationalist identities, such as the Scots in *Great Britain*, and asserting new political rights – transforming intrastate politics into imperial politics. Even as the overseas empires have ended, a new age of imperial struggle is emerging.

This new age will be politically more complex than the old. The principle of national self-determination, articulated by President Woodrow Wilson at the *Versailles Peace Conference*, could be easily employed in the fight against overseas empires. Today, this principle directly contradicts contemporary notions of sovereignty as an inviolable whole. As demonstrated in the *NATO* intervention in *Kosovo*, Western nations abhorred the political domination of the local Albanians by their *Serb* rulers, but they could condone the breakup of a sovereign state only as a last resort. As both old and new imperial relationships within multinational states become contested, politicians and analysts alike will need to rethink issues of political identity, statehood, and empire and perhaps experiment with new forms of political hierarchy.

Interest in imperialism as a term and concept has also waxed with the rise of US unipolarity after the end of the Cold War and, especially, the Iraq War of 2003. As in its first use as a critique of Napoleon's ambitions in Europe, critics of the US war against Iraq charged the Bush administration with imperialism. From a rare term in political discourse, seldom uttered since the Vietnam War, the phrase 'American empire' appeared over 1000 times in US newspapers between December 2002 and the start of the war in May 2003. The term was also taken up by a slew of authors (among others, see Bacevich, 2002; Ferguson, 2004). In describing the United States as imperialist, critics sought to characterize the war as an illegitimate use of power against another sovereign state. Yet, the term was also embraced by the Bush administration, as when an unidentified but high-ranking official told reporter Ronald Suskind, "We're an empire now, and when we act, we create our own reality." With the end of the Iraq War, the use of the term has once again waned. Nonetheless, its long history as both practice and invective ensures that imperialism will remain a robust political relationship into the future and a deep source of disagreement and discord in world politics.

Abstract

The word 'imperialism' is one of the most powerful concepts of our time. Originally coined as a term to describe and analyze the expansion of the European powers over the rest of the world in the last quarter of the twentieth century, the term was soon employed to also characterize a particular stage in the development of capitalism, especially by Marxist thinkers, and later developed into an invective for describing the activities of one's political adversaries. In scholarly writing, the word mostly indicates the extension of what was largely European formal or informal political rule over Asian and African countries in the late nineteenth and twentieth centuries. It also serves more generally to describe some other forms of Western predominance during and after the colonial period. Prior to the end of the Second World War, an economic interpretation of imperialism was prevalent, but after that time, other theories were brought forward giving more attention to other aspects, particularly political ones. More recently, the primacy of economic interpretations, especially of British imperialism, has been reasserted. In the vast literature on British, French, German, Italian, Portuguese, and Dutch imperialism that developed from the 1960s onward, the various national forms of this general European phenomenon have been studied. The rather different cases of Russian, American, and Japanese expansion have also been analyzed from the perspective of the theory of imperialism. In modern scholarly literature, imperialism is no longer conceived of as a unilateral process imposed by a dominating power but as a process of interaction between the metropole and the periphery.

Introduction: The Problem of a Definition

"Imperialism is not a word for scholars", Sir Keith Hancock remarked a long time ago, and he was right (see Wesseling, 1997: p. 74). More recently, Bernard Porter has written that "'Imperialism' is a much vaguer term than 'the empire'. Its extent and limit are less definite, and for that reason open to interpretation and dispute" (Porter, 2012: p. 4). Scholars have to make clear what they mean when they use certain concepts or terms, and therefore have to provide definitions. This, however, is problematic with the word 'imperialism'. The difficulty is not that there is no single definition of imperialism. Rather, there are about as many definitions of imperialism as there are authors who have written on the subject. They vary from those that refer to one specific form of imperialism, mostly Europe's nineteenth-century colonial expansion, to others that give a very general meaning to the word, such as the one in Webster's Dictionary: 'any extension of power or authority or an advocacy of such extension'. Clearly, such a definition can cover almost any situation involving a stronger and a weaker power. Not surprisingly, therefore, the word has often simply been used pejoratively in order to criticize the policy of another country. With some justification, P.J. Marshall has noted: "'imperialism' has tended to become a term of abuse for any supposed domination which the speaker happens to dislike" (Marshall, 1982: p. 49).

Used in this context, the term imperialism is of little scholarly value. However, in academic studies, the word has always had a more limited meaning. The problem is exactly how limited its meaning should be. Sometimes the word is used in a universal historical way in order to characterize the politics of a dominant power. Thus, some historians have spoken of Roman or even Assyrian imperialism, but this is highly exceptional. John Darwin has succinctly defined imperialism as the "sustained effort to assimilate a country or region to the political, economic or cultural system of another power" (Darwin, 1997: p. 614). In historical studies, imperialism generally refers to the policy of European countries, and primarily of Britain during the nineteenth and twentieth centuries, aiming at the expansion of their power and influence over other continents. It is in this context that the term imperialism originated and began to be used as a political and historical concept. Historically speaking, the word imperialism is therefore obviously closely associated with colonialism. While colonialism was only used to refer to one specific form of alien rule, namely, the colonial one, imperialism acquired a wider meaning and included various other forms of influence over alien nations and states, for example, the financial influence of France and Germany in the Russian and Ottoman Empires, or such ideas as British 'gunboat policy' and American 'dollar diplomacy'.

After the end of the colonial empires, the word 'colonialism' could only be used to refer to a phenomenon from the past and thus began to fall out of use. 'Imperialism', however, continued to be used, and from then on also indicated those forms of domination that were formally different from, but factually comparable to, those formerly practiced by the colonial powers. For a while, the word 'neocolonialism' was also used for this purpose, but somehow this term was less successful. By the end of the Second World War, America had become the new superpower. Accordingly, imperialism was now mainly applied to describe the foreign policy of the United States vis-à-vis other countries, in particular in Latin America, Asia, and Africa (Ferguson, 2005). There was also an attempt to make the concept applicable to the policy of the Soviet Union with regard to the Central and Eastern European countries that came under its influence after 1945 (Seton-Watson, 1961), but this was not very successful. The reason for this is that historically speaking, imperialism has connotations with capitalism and not with communism, and with overseas possessions, and not

with adjacent countries. Although there clearly was a Soviet Empire, it was not considered to be an example of imperialism but of traditional power politics. Only in its very general meaning as another word for all forms of power politics or simply as an invective, was it also used to describe communist countries such as the Soviet Union and China. After the end of the Cold War, this use of the word imperialism lost much of its earlier attraction.

In this article, imperialism is used in the sense of its initial meaning, that is to say as a term to indicate the extension of formal or informal, mostly European, rule over Asian and African countries in the late nineteenth and early twentieth centuries as well as, more generally, for some other forms of Western predominance during and after the colonial period.

Imperialism: The History of a Concept

Like 'colonialism', which was probably first used in the title of a book of a French socialist critic of the phenomenon, Paul Louis' *Le Colonialisme* from 1905, 'imperialism' was originally a French word. It was from the 1830s onward that the terms *impérialiste* and *impérialisme* came into use in France. They referred to the empire of Napoleon and to the imperial pretentions of his nephew Louis Napoleon, later known as Napoleon III. The colonial connotation only came after the word had begun to be used in the United Kingdom in the 1860s. Then, of course, the empire it referred to was no longer the continental one of France but the overseas empire of Great Britain (Koebner and Schmidt, 1964).

Although the word imperialism was already used in the United Kingdom in the 1860s, the historical concept only appeared in 1902 with the publication of J.A. Hobson's *Imperialism: A Study* (Hobson, 1938). Hobson, a radical but not a socialist, was deeply influenced by the South African War (1899–1902). In 1900, he published a book on this subject, *The War in South Africa. Its Causes and Effects*, in which he argued that power in South Africa had fallen into the hands of a small group of financiers "chiefly German in origin and Jewish in race" (Hobson, 1900: p. 189). In his famous book *Imperialism: A Study*, he elaborated this vision into a general theory of imperialism, and used the term imperialism to indicate the "expansion of Great Britain and of the chief continental Powers" (Hobson, 1938: p. 27). The word expansion referred to the fact that over the previous 30 years, a number of European nations, Great Britain first and foremost, had "annexed or otherwise asserted political sway over vast portions of Africa and Asia, and over numerous islands in the Pacific and elsewhere" (Hobson, 1938: p. 15). For Hobson, the meaning of the word imperialism was very clear: it was the establishment of political control. He was also explicit about the forces behind it. Various people such as an "ambitious statesman, a frontier soldier and an overzealous missionary" might play some role in it, "but the final determination rests with the financial power" (Hobson, 1938: p. 59). Thus Hobson offered us a definition (imperialism is the expansion of political power of European countries over the non-European world), a periodization (imperialism took place over the previous 30 years, thus between 1870 and 1900), and an explanation (it was the result of the workings of the financial powers). In order to explain their behavior, Hobson argued that, as a consequence of the capitalist system, the British economy suffered from underconsumption. As a result of this, surplus capital could no longer be invested profitably in England itself. Therefore, the capitalists were "seeking foreign markets and foreign investments to take off the goods and capital they cannot sell or use at home" (Hobson, 1938: p. 85). "It is not too much to say that the modern foreign policy of Great Britain has been primarily a struggle for profitable markets of investment", adumbrated Hobson, who concluded that "It is this economic condition of affairs that forms the taproot of imperialism" (Hobson, 1938: pp. 53, 81).

The originality of Hobson's explanation for imperialism has been questioned by Gregory Claeys who contends that the economic side of his ideas was "if more sophisticated, methodical and carefully crafted, none the less the stock-in-trade of both Positivist and much socialist argument, built up over the previous half-century" (Claeys, 2010: p. 246). However, as Hobson's theory implied a criticism of capitalism, it had a palpable attraction for Marxist thinkers. As a result of this, a new Marxist theory of imperialism was born. While originally Marx and Engels had considered colonialism as an 'objective' progressive force (Avineri, 1968), now Marxist theorists such as Karl Hilferding and Rosa Luxemburg scorned late-nineteenth-century imperialism as a form of exploitation and suppression. The Marxist theory of imperialism became very influential when it was appropriated by a man who was not only a theorist but also a practical politician, Lenin. In 1916, he published his famous brochure *Imperialism. The Highest Stage of Capitalism* (Lenin, 1916). While Hobson perceived imperialism as a malfunctioning of capitalism, Lenin saw it as a sign of its ultimate and inevitable decay.

Lenin's ideas were mostly based on the work of the already-mentioned Marxist authors, who in turn had been inspired by Hobson's theory. It was therefore understandable that a direct link was seen between Hobson's and Lenin's theories, so much so that it became fashionable to speak of the 'Hobson–Lenin thesis'. There are, however, two important differences between Hobson and Lenin. First, for Hobson, the flight of capital from the metropolis to the overseas world was a consequence of the development of capitalism, but not a necessary consequence. The origin of the problem was underconsumption. Therefore, theoretically, it should also be possible to solve the problem by increasing the purchasing power of the working classes. Indeed, Hobson remarked: "If the consuming public in this country (Great Britain) raised its standard of consumption to keep pace with every rise of productive powers, there could be no excess of goods or capital clamorous to use Imperialism in order to find markets" (Hobson, 1938: p. 81).

Second, and more importantly, Hobson and Lenin tried to explain two different things. Hobson, who wrote his book during the South African War, wanted to explain the division of the world, and more specifically of Africa, in the late nineteenth century. Lenin, who wrote in 1916, tried to explain the redivision of the world of which the First World War was the most spectacular outcome. The word Africa hardly appears at all in Lenin's brochure. The period he referred to was also different from the one dealt with by Hobson: not 1870–1900 but thereafter. He wrote explicitly about this: "I have tried to show

in my pamphlet that it (imperialism) was born in 1898–1900, not earlier" (see Stokes, 1969: p. 289). Thus Lenin parted ways with Kautsky and Luxemburg, for whom imperialism was little more than another word for colonialism (Stokes, 1969: p. 297). For Lenin it was something else: not the highest stage of colonialism but of capitalism.

Although the capitalist theory of imperialism was not generally accepted, and alternative interpretations were launched and had some influence, some form of economic interpretation became the standard explanation of imperialism during the 1920s and the 1930s. Imperialism was considered as having originated from economic problems in Europe that were characteristic of the late nineteenth century, in particular the need to guarantee the flow of raw materials to the industrialized countries, and the protection of overseas markets for the sale of their industrial products. This consensus broke down after the Second World War under the influence of decolonization and the rise of the American Empire. The new world political situation also had an impact on the theory of imperialism. In a celebrated article, 'The Imperialism of Free Trade', two Cambridge historians, Jack Gallagher and Ronald Robinson, developed the concept of 'informal empire' (Gallagher and Robinson, 1953). They argued that the real zenith of the British Empire was not to be found in the late nineteenth century but rather in the mid-Victorian period of informal British economic hegemony. For Britain, the entire nineteenth century was one of expansion. It was an imperial century. Britain's imperial expansion manifested itself in various forms: emigration, trade, overseas investments, the establishment of naval bases, etc. The extension of political authority over foreign people was only one form of imperialism, and not even the most important one. The mid-Victorian Empire was comparable to the informal American Empire that came into being after 1945. It worked with informal means because that was the best way of doing things. The maxim of British policy makers was: informal empire if possible, formal only if necessary. Due to foreign competition and rivalry, however, the late Victorians were forced to formalize their Empire, and they did so, willy-nilly.

While Gallagher and Robinson discovered imperialism before empire, other theorists also discovered imperialism after empire. This resulted not so much from a reflection on the rise of the American Empire, but from a reassessment of decolonization. While after the First World War the European powers had increased their territorial possessions – for example, by the division of parts of the Ottoman Empire – and stabilized their colonial rule, the situation was very different after the Second World War. In Asia, the process of decolonization started immediately after the war and was followed later in Africa. Thus, by the 1960s, most of the former colonies had become independent politically. But political independence did not automatically bring an end to the social problems, nor to the economic dependency of the excolonies. Some of the new states became even more dependent on the Western-dominated world system than they had been before. For many observers, it was clear that the end of empire was not at the same time also the end of imperialism. Some theorists worked this out in the theory of dependency. According to the *dependencianistas*, imperialism not only was the extension of political control but also included the dependency of less developed parts of the world on the industrial powers. Empire was only one form of imperialism, one stage in the history of Western dominance.

However, why one form of imperialism was replaced by another remained a question, an answer to which was also given by Gallagher and Robinson in their famous book on the partition of Africa: *Africa and the Victorians* (Gallagher and Robinson, 1961). Here, they argued that changes in the periphery, that is, in the overseas world rather than in the mother countries, were responsible for the changes in the ways and means of imperialist control. Although *Africa and the Victorians* dealt primarily with British policy, the theories developed here had a wider meaning. While the theory of the imperialism of free trade was typically a theory about British imperialism, the peripheral theory was applicable to the imperialist activities of other nations as well. In many cases, changes in the non-Western world were decisive in determining imperialist action. Egypt's financial problems, for example, led to increasing foreign interference, and this, in turn, led to a 'nationalistic', or rather proto-nationalistic, reaction that plunged Egypt into an internal political crisis that led again to foreign intervention and occupation. The discovery of minerals in South Africa, to give another example, led to a complete change in the balance of power in that part of the continent.

Ronald Robinson later elaborated this interpretation into a more general theory based on the observation of the important role of the African and Asian partners of the imperialist rulers. In this so-called collaborationist theory, imperialism is conceived of as a system of collaboration between European and non-European forces before, during, and after colonial rule. The changing forms of imperialism are considered as changing forms of collaboration that resulted from changes in the bargaining positions of the various parties (Robinson in Owen and Sutcliffe, 1972: pp. 117–142).

The Gallagher and Robinson theories were followed by a greater number of studies on the economic significance of the British Empire and the role of economic factors in British imperialism. Foremost among these were a number of seminal contributions by P.J. Cain and A.J. Hopkins. "Explanations of imperialism", they contended, "ought to begin with a close study of economic structure and change in Britain" (Cain and Hopkins, 1987: p. 17). In particular, they argued that nonindustrial forms of capitalism, especially those associated with financial and commercial services based in the City of London, had been underestimated. They proceeded to assert that it was "in the second half of the nineteenth century, and especially after 1870, that Britain's expanding financial power created a world-wide 'invisible empire' which compensated for her dwindling economic influence in the United States and Europe" (Cain and Hopkins, 1987: p. 11). In Cain and Hopkins' interpretation, the essential link between Britain's expanding financial sector and imperialism was provided by 'gentlemanly capitalists', landowners, and financiers from southern England who boasted the same social background and inculcated similar notions of national interest as the aristocratic governing class. In his quasi biography of Hobson, Cain has maintained that "Where Hobson went wrong was in his forthright view of the relationship between finance and politics: finance was often crucial to expansion, financial conspiracy was not. Even in Egypt, where the financial motives

for occupation were obvious, there is no evidence to support Hobson's continuously reiterated assertion that ruthless financiers manipulated much less visionary and hesitant politicians to serve their clearly understood ends" (Cain, 2002: pp. 277–278). Although Cain and Hopkins have drawn criticism, not least their tendency to focus on gentlemanly capitalists to the exclusion of other important influences on British imperialism, their work has also found admirers (Webster, 1998).

While examining British imperialism beyond a simple concentration on gentlemanly capitalist interests, John Darwin places economics at the heart of the explanation for British imperialism: "It was coal, cotton and capital, not derring-do or district officers, on which Britain's world empire was built" (Darwin, 2012: p. 394). He also seeks to downplay the role of the 'official mind' in the growth of the British Empire. "British expansion", he insists, "was driven not by official designs but by the chaotic pluralism of British interests at home and of their agents and allies abroad" (Darwin, 2009: p. 3). More specifically, Darwin observes that "Since the prime motive was profit not the glory of Church or king, this was an empire of commercial experiments not an empire of rule by design" (Darwin, 2012: p. 389). As such, he points out that the "hallmark of British imperialism was its extraordinary versatility in method, outlook and object" (Darwin, 2012: p. 388). The impact of imperialism on Britain itself is a contested issue that has drawn contrasting interpretations regarding the depth of its imprint on the metropole (Porter, 2004; Thompson, 2005).

The important place of Britain in the debate on imperialism is understandable, because Britain was the imperial power par excellence. Some historians have suggested that British imperialism 'made' the modern world or even acted as a progenitor of modern globalization (Ferguson, 2004; Darwin, 2008). Nevertheless, Britain was by no means the most typical imperial power. Rather, it was atypical and therefore the discussions in other European countries on imperialism have followed different lines and focused on different questions. Chronologically speaking, however, the European revisionist theories were developed in the same years as the British: the debate started in the 1960s and continued well into the 1980s and beyond.

National Articulations

In France, Henri Brunschwig's *Mythes et Réalités de l'Impérialisme Colonial Français*, 1871–1914, which appeared in 1960, set the tone for the debate on French imperialism (Brunschwig, 1960). According to Brunschwig, the causes of French imperialism were not to be found in economic demands but in the development of French nationalism after the defeat in the Franco-Prussian war of 1870. The protectionist factor was a myth; political factors were decisive. Given the specific intellectual climate that existed in France after the Second World War, and in which Marxism played such an important role, it was to be expected that Brunschwig's book would lead to great controversy, as it did. But the Marxists could hardly deny the fact that the French colonial empire had been of little economic importance in France. In order to rescue the Marxist theory of imperialism, they therefore argued that French imperialism was not to be found in the French colonies but elsewhere, in the Russian and Ottoman Empires. They argued that French colonialism was not imperialist, and French imperialism was not colonial (Bouvier and Girault, 1976). In 1984, an important study by Jacques Marseille, based on an extensive data bank on French colonial trade, threw new light on the question of economic interest. His conclusion was that in the beginning the colonies were useful to French industry from an economic point of view, but subsequently they became a burden (Marseille, 1984).

There was also a strong connection between imperialism and nationalism, but it is not altogether clear to what extent imperialism was a result of nationalism. This is because the decision to found a German colonial empire was very much the decision of one man, Chancellor Bismarck. Therefore, in Germany, the discussion on imperialism has always been concentrated on Bismarck and his motives. There were two main interpretations: a foreign political one (imperialism as a move in Germany's international relations) and one in terms of domestic policy, such as electoral success, financial pressure groups, etc. The discussion was reopened when H.U. Wehler (1969) added new elements to this debate. Although he stressed the economic background of imperialism, he agreed that, as in the case of France, the German colonial empire had not been very profitable. In his view, the link between economics and empire must be sought on a different level. He emphasized the social problems of the *Reich* (its lack of legitimation because of its creation *von oben*, by force) and considered Bismarck's bid for colonies as a shrewd political move intended both as part of a general, more or less anti-cyclical, economic policy and of a social policy seeking to unite the Germans around issues of foreign policy, and thus to overcome internal tensions. Thus Wehler's emphasis was more on the domestic than on the diplomatic motives of German imperialism under Bismarck (Wehler, 1969). Here, the debate on German imperialism touched upon a wider discussion, the one on the problem of continuity and discontinuity in German foreign policy, the so-called German *Sonderweg*, and the place of national socialism in German history.

Italian imperialism was also studied from a special perspective. It was not very successful during the classical period of imperialism but it continued during the interwar years, under the influence of fascism. The French historian Jean-Louis Miège has emphasized not only the demographic factor in Italian imperialism but also its political and ideological dimensions – the nationalistic reaction to the loss of population as a consequence of emigration – comparing it in this respect to Spanish imperialism (Miège, 1968). The interpretation of Portuguese imperialism was long dominated by Hammond's theory of an 'uneconomic', that is to say a primarily nationalistic, form of imperialism. Gervase Clarence-Smith later challenged this view by making a strong case for an economic interpretation of Portuguese imperialism. He argued that economic motives went hand in hand with other ones such as missionary zeal and nationalism (Clarence-Smith, 1985).

The case of Belgium is very special, because in the nineteenth century, Belgium was an anti-colonialist country, but in spite of this, it was eventually to acquire one of the biggest

European colonies in Africa, the Belgian Congo (later called Zaire, now Congo again). That this happened was due to the extraordinary zeal, tenacity, ruse, and ruthlessness of one man, King Leopold II. Jean Stengers has analyzed the singular nature of the king's imperialism, which was one of old-fashioned economic exploitation and in this respect inspired by the example of the Netherlands (Stengers in Owen and Sutcliffe, 1972: pp. 248–276).

In the Netherlands, the historical discussion on imperialism began rather late. The most important contribution to the debate came from a book by Maarten Kuitenbrouwer (Kuitenbrouwer, 1991). In this he argued that the Dutch case was roughly analogous to others, and that the Netherlands followed more or less the general pattern. It has also been noted, however, that Dutch imperialism was defensive rather than offensive, reluctant rather than enthusiastic. In this respect it was comparable to that of Britain. In both cases, there was more continuity than discontinuity, and what discontinuity there was, derived from a change in circumstances, not in policy (Wesseling, 1997).

The historical debate on imperialism was mainly about the traditional colonial powers of Western Europe but observations have also been made about other countries. Russian imperialism poses interesting questions and offers paradoxical aspects because, on the one hand, Russia was an object of Western European financial imperialism, but on the other, it was itself also acting as an expansionist power by extending its empire to the East and eventually to the shores of the Pacific (Geyer, 1977; Le Donne, 1997). The case of Japan is particularly noteworthy because it is the only Asian nation that became an imperial power. In keeping with other Asian countries, it was first confronted with Western influence but it reacted in a very different way to this challenge. After having been forced to 'open' the country in 1853, it accepted Western notions and techniques very rapidly, so much so that already by the 1890s it had started its expansion into China. Japanese imperialism was continued in the 1930s and of course during the Second World War. Some analysts have also considered Japan's economic expansion after 1945 as a form of informal imperialism (Mommsen and Osterhammel, 1986: pp. 53–82).

The concept of American imperialism is a very complicated one, not only because of its origins as a former colony that engaged in a violent struggle to disengage from the British Empire but also because of the fact that it has prided itself on its anti-colonial rhetoric. The foremost historian of American imperialism is arguably Niall Ferguson. Ferguson in many ways sees America as the postwar successor to British imperialism, arguing that "in terms of economic resources as well as of military capability the United States not only resembles but in some respects exceeds the last great Anglophone empire" (Ferguson, 2005: p. 19). For Ferguson, the American Empire resembles its mid-nineteenth-century British predecessor since it "preferred indirect rule to direct rule and informal empire to formal empire" (Ferguson, 2005: p. 12). Also seeking to link British and American imperialisms, Bernard Porter observes that "The continuity does not lie in the imperialisms *per se* – America simply inheriting Britain's imperialism from her … – but in the underlying process that carried both of them. That was the 'progress' of the world towards globalization, free markets, consumerism, liberalism and the all the rest: the 'end of history', *perhaps*. This is the fundamental historical trend. Modern imperialisms are just corks, bobbing along the surface of them" (Porter, 2012: p. 316). For Ferguson, nevertheless, the American empire is a curious form of imperialism; as he puts it: "The United States has acquired an empire, but Americans themselves lack the imperial cast of mind. They would rather consume than conquer" (Ferguson, 2005: p. 29). As such, Ferguson depicts American imperialism as "an empire in denial" (Ferguson, 2005: p. 294).

For John Darwin, the preeminent historian of global empires, it is the case that "Imperial power has usually been the rule of the road" (Darwin, 2008: p. 23). As such it is axiomatic that the United States has become an imperial power. "After 1990", he asserts, "it became the only world empire. A state with the means to intervene forcibly in almost any part of the world, with such a massive advantage in military power over any possible rival, and with an advanced economy more than twice the size of its nearest competitor was such an empire de facto" (Darwin, 2008: p. 482). That the United States has lacked the colonial possessions of its Victorian predecessor, insists Darwin, is of "trivial importance" (Darwin, 2008: p. 483).

Explanation: Motives and Means

The rich literature on imperialism that has been published from the 1960s onward has led to a revision of the traditional views on the origins and meaning of late-nineteenth-century imperialism. Transformations not only in Europe but also in the overseas world have received attention as factors that can explain the new imperialist attitude. The main distinction is between European interpretations on the one hand, which underline economic, political, strategic, and ideological motives, and peripheral interpretations, which give special attention to activities and developments in the overseas world and in particular to the 'frontiers' of European influence. The new research has also given attention to such topics as the ecological aspects of imperialism (Crosby, 1986), cultural imperialism (Said, 1978, 1993), the impact of imperialism on the sciences (Petitjean et al., 1992), and so on.

Much of the debate on imperialism concerned the motives of the imperialists. In order to understand the origins of imperialism, however, attention has also to be given to another aspect, not the motives but the means. The development of imperialism cannot be understood by looking only at transformations in Europe and the overseas world, and the incentives for imperialist actions that were created by these. What also was essential for such action was the possession of the necessary means (Headrick, 1981, 1988). It had always been virtually impossible for Europeans to survive in the environmental conditions of tropical Africa. New developments in the medical sciences, such as the prophylactic use of quinine (as from the 1840s), made it possible for Europeans not only to live but also to work and even to fight under such conditions. The development of new means of transportation (steamships, railways), the opening of new sea routes (like the one via the Suez Canal), and the revolution in the means of communication (the telegraph, and later on the telephone and wireless communication) made the extension of imperial rule possible.

Finally, but perhaps most importantly, the development of new weapons, and in particular of the machine gun, gave the Europeans an enormous advantage in their battles with non-European nations. Colonial wars became successful almost by definition and the European colonial armies became 'ever-victorious' armies. Entire continents could be conquered at very small cost to the conquerors.

Thus the great technological superiority of the Europeans came into existence during the later part of the nineteenth century due to the so-called Second Industrial Revolution that took place in Western Europe and created rivals for British trade. These technological transformations not only offered the means for imperial expansion but also led to new demands in the European societies, which had their effects on foreign and colonial policy. Social and economic questions assumed increasing importance. State welfare provisions expanded. The import of tropical products at affordable prices was considered as a matter of public concern. This called for sustained economic exploitation, which presupposed the existence of peace and order; in other words, effective authority.

The balance of power in Europe also changed dramatically in the 1870s. In the early nineteenth century, from Napoleon to Bismarck, Europe had found itself in an exceptional political situation. Germany and Italy did not yet exist. Britain had eliminated France as a maritime and colonial rival. Spain, Portugal, and the Netherlands, the old colonial powers, had had their day. Hence, Britain enjoyed *de facto* world supremacy, much as the United States was to do after the Second World War. All these factors began to be compromised from the 1870s. After its defeat in 1870, France sought compensation for its loss as a continental power by strengthening its overseas role. Germany and Italy, newcomers both, claimed a place under the sun.

Internal political factors also played a part. European governments were faced with a new phenomenon: they had to take the wishes of their electorate into account. Economic growth and social harmony became declared objectives of government policy. The Paris Commune of 1871 accentuated the danger of social revolution and hence the importance of social issues. The state was asked to do more things for more people. Conversely, technical progress, economic growth, and growing political involvement by the citizens of Europe created the conditions for a strong state. The military might of the European powers reached unprecedented heights. At the same time in the overseas world, transformations took place, which often proceeded from previous contacts with Europe or European settlers, and which changed the existing internal balance of power. Thus in many respects, a new situation came into being after 1870, in Europe as well as in the overseas world, and therefore, after all forms of revisionism, it is still justified to speak of the period of 1870–1914 as an age of imperialism, as Hobson did when he introduced the concept over a century ago. That imperialism is still with us, either in the form of contemporary globalization as writers such as Michael Hardt and Antonio Negri suggest (Hardt and Negri, 2000), or in the rise of an informal American Empire in the postwar world as Darwin, Ferguson, and others contend, demonstrates the vitality of the concept and its ongoing relevance to the contemporary world.

Implementation: Political

Eugene Bardach, Goldman School of Public Policy, University of California at Berkeley, Berkeley, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Once adopted, a policy must survive the rigors of the implementation process. These often lead to delay, the perversion or diminution of goals, and costs higher than expected. The causes generally lie in the many, and sometimes complex, elements that have to be brought together in a workable fashion, and in the many actors, with diverse priorities and objectives, who control those elements. Countervailing strategies involving leadership, momentum, and strategic retreat may somewhat offset these difficulties.

Implementation studies are inevitably normative. In 1973, the field was created virtually overnight by Jeffrey Pressman and Aaron Wildavsky, in whose book *Implementation* the guiding research questions were: "How well was this authoritative mandate (law, regulation, program, official policy pronouncement) implemented?" and "How might it have been better implemented?" Later researchers redefined the normative standard as achieving the values implicit in some mandate rather than in executing its prescriptive details. Then the guiding question became: "How can a complex implementation process bring out the values implicit in, or improve upon the raw materials provided by, some authoritative mandate?" Such normative questions have provided an intellectual focus for a field unified by little else.

'Successful Implementation' Defined

For simplicity, I restrict discussion to legislative mandates. The raw materials are typically (1) a legislative mandate, (2) some new budgetary resources, and (3) a designated responsible agency. In most circumstances these three assets are not enough and other resources are needed. Mandates defining regulatory programs will often require compliance resources from businesses or ordinary citizens. Service-delivery programs will often need participation from citizens who perceive the availability of the program, are willing to make the effort to establish eligibility, and can manage to sustain continued participation. The responsible agency may also wish to involve relevant nonprofit agencies. Other program agencies with overlapping jurisdictions or responsibilities must sometimes be asked to cooperate. Overhead agencies must supply permission to recruit personnel, lease office space, enter into contracts, and so on. 'Implementation' is therefore a process of constructing an operational program out of both newly mandated and extant resources. 'Successful' implementation means that the result is faithful to at least a minimalist interpretation of 'the mandate,' is at least minimally cost-effective, and is produced without unacceptable delay. (For a time scholars were divided into 'top-down' and 'bottom-up' camps, depending on where in the loose hierarchy of actors in the implementation process they preferred to look for the more important causes of failure or success and for the normative interpretation of 'the mandate' being implemented. This division is no longer meaningful, however (O'Toole Jr., 2004).)

Explaining Success and Failure

The early implementation literature, inspired by the troubles of Great Society programs, focused on documenting and explaining implementation failure. The (partial) subtitle of *Implementation* was "How Great Expectations in Washington Are Dashed in Oakland; Or, Why It's Amazing that Federal Programs Work at All…" The principal explanatory framework in the early literature highlighted the institutions and practices of American pluralist and federalist democracy that were unfriendly to implementation, e.g., the large number of actors that had to be brought into the process, the susceptibility of programs to continuing political conflict over their goals and resources, weak or nonexistent interagency and interjurisdictional coordinating systems, and cumbersome accountability procedures and heavy-handed overhead agencies. In this world of fragmented political power, the many resources required for program construction are controlled by different actors – from front-line regulatory enforcers and service professionals to personnel officials writing civil service job descriptions – with only partially overlapping interests and with highly variable abilities and motivations to induce cooperation among one another (Nakamura and Smallwood, 1980). Furthermore, these actors normally – and often quite properly – have different priorities than those of the advocates for the new mandate. They have ongoing responsibilities, after all, some of which are poorly fulfilled as it is, given normal governmental resource constraints.

Consider these institutional problems in system terms. Constructing a complex operational system out of many, varied, and interdependent elements is vulnerable to failure from many quarters. Bureaucratic resistance, prolonged bargaining, political sabotage, weak technical capacity, and a host of other conditions could affect many of these elements (Bardach, 1977). Failure seems overdetermined. Yet failure appears to be much less frequent than this model suggests (O'Toole Jr., 2012). The model omits the possibility of adaptation, i.e., strategically sacrificing controversial or overly ambitious goals and creatively improvising with respect to means. It also omits momentum, the fact that success with

respect to securing one system element helps to beget success with respect to others.

The capacity to plan and execute effective adaptation and momentum-building strategies often takes the form of committed political leaders, entrepreneurial program managers, clever legislative staff and their principals, and the like (Mazmanian and Sabatier, 1983; O'Toole Jr., 2004). This, at least, is the impression conveyed by many of the case-study reports of successful implementation. Although lacking a methodological and theoretical rationale, such case studies may, nevertheless, have illuminated an important phenomenon. The current theoretical challenge of greatest significance is to explicate the process of adaptation and to identify factors that increase the likelihood of success or failure. The corresponding empirical challenge is to identify the conditions under which skilled adaptive leadership is drawn into certain implementation processes but not into others.

Design Failures and Implementation Failures

The early literature usefully distinguished failures of implementation from three common design-stage mistakes that simply show up *during* the course of implementation and which might have been aggravated (or occasionally ameliorated) by the implementation process. First, design-stage expectations are usually too high. To survive the legislative process, a policy or program mandate will often have had its merits oversold and its limitations understated. Second, designers sometimes commit fundamental conceptual errors, e.g., supposing that price controls in competitive markets can be implemented without causing shortages. Third, they may choose an inappropriate policy instrument. Arguably, the programs studied by Pressman and Wildavsky, concerning the subsidized creation of low-skill jobs in a poor city, represented failures of instrument selection. The chosen instrument was a subsidy to firms promising to hire from a general target population. With no easy way to enforce the promises, however, the implementing agency probed the prospective employer firm for months on end, trying to clarify what might count as a legitimate excuse for underperformance and trying to test the firm's good faith and resolve. A much better choice of instruments would have been an ex-post-facto wage subsidy for workers actually hired.

The Characteristics of Generic Governmental Instruments

In the literature 'implementation problems' also include those that beset most operational governmental programs. Although the early implementation literature focused on 'control' problems, the focus is now broader, encompassing the standard problems of public administration and public management, e.g., how to recruit good personnel and motivate quality performance, how to keep a focus on results rather than on personal or careerist objectives or simply on following procedures and staying out of trouble, how to protect the program from ideological opponents in the legislature or within the cadre of higher-level political appointees, how to build trust and communications channels within and across agencies, and how to create a culture of continuous improvement. The 'reinventing government' movement has been a modest source of ideas and inspiration about how to cope with general management problems.

But the distinctive contribution of implementation research regarding such problems has been to analyze the forms they take when expressed in generic governmental instruments (Salomon, 1989). Two of the most important of these are regulation (e.g., sanitary code enforcement and electric utility rate setting) and pure service delivery (e.g., employment and training) either directly or through provider subsidies.

Regulation

Command-and-control (or 'social') regulation is typically a response to information failures – regarding unsafe bus maintenance, say, or filth in restaurant kitchens – which prevent consumers or employees from protecting themselves through either market action or the threat of lawsuits. Command-and-control programs typically have four main components: a set of standards, a cadre of inspectors and auditors to detect noncompliance, a set of sanctions with which to threaten noncompliant firms or citizens, and the climate of deterrence (or prevention) that these three elements create in combination. This sort of regulation is vulnerable to errors of underregulation or overregulation or to both simultaneously. Political pressures and scientific uncertainty can lead to overly stringent or overly lax standards. Standards can also be too prescriptive or too ambiguous. The enforcement process is vulnerable to budgetary strictures, overconcentration on symbolic targets, go-by-the-book rigidity, and in some cases corruption. Deterrence can be weak and pale or else overweaning and overly broad. And overall, regulatory strategies do not necessarily take account of the capacity, or lack of it, of the targeted parties to actually do what is nominally required.

Economic regulation includes natural monopolies such as local telephone service and (former) oligopolies such as long-distance freight hauling. Most scholars observe that the regulators tend to get 'captured' by the more powerful firms within the regulated industry. Arguably, the regulators are as much captured by a sense of responsibility for the economic well-being of the industry they regulate, however, and allow 'well-being' to be interpreted through the self-interested lenses of the major firms.

Technological change and more realistic economic analysis have undermined the rationale for much traditional economic regulation, and many regulatory activities, along with a few agencies, have been abolished. A new addition, however, has been environmental regulation. Although it often uses command-and-control methods, it also counts as 'economic' regulation because implementers are concerned with how their decisions on standards and enforcement actions affect inter-firm, interindustry, and interregional competitive balances.

Service Delivery

The chief implementation challenges in service-delivery programs are developing technically effective services (as in effective teaching of third-graders); suppressing fraud, waste,

and abuse (as in $2 billion in fraudulent Medicare billings); and preventing inequitable distribution to constituencies favored by politics or by the preferences of service professionals (as in middle-class neighborhoods, tending to attract better teachers to their schools). A fourth challenge is keeping service quality at a high level while being unable to rely on traditional market-based incentives such as the threat of consumer exit.

When government uses subsidies to enlist private providers, such as hospitals treating Medicaid patients or nonprofit organizations to provide vocational training, it typically relies on regulations and audits to attempt to ensure that the providers are targeting their services correctly, maintaining a minimal acceptable quality, and not engaging in fraud or abuse (McDermott, 2004). Many of the problems of command-and-control regulation are thereby imported into service-delivery programs.

Service programs aimed at 'deviant' populations such as drug abusers, criminal offenders, the mentally ill, and welfare recipients typically have a regulatory, paternalistic component as well as a pure service component. Implementing personnel usually have considerable discretion over how to balance the two components (May and Winter, 2007; Lipsky, 1980). Large-scale ideological trends, and more immediate political pressures, also affect the balance.

The Practitioner's View of Implementation

Because implementation studies are normative, their results can be helpful in guiding practice. The literature advises policy designers to: (1) 'map' the functional requirements of a projected operational system and how they are each to be obtained (Elmore, 1979), (2) write 'scenarios' regarding possible implementation pitfalls en route to such a system (Bardach, 1977), and (3) estimate the probability of 'compliance from target groups' whose cooperation is needed for critical tasks (Mazmanian and Sabatier, 1983). O'Toole (2004) has recommended heuristics from game theory and from 'contextual interaction' theory, which focuses on the objectives, information, and power of the 'basic sets of actors.' Designers can also consider institutional solutions, e.g., contracting with an organization in the private sector to take on the responsibility of starting and running a new AIDS clinic or building and operating a new jail.

Implementers can also view the experience of operational implementation, whether successful or otherwise, as a way to improve long-run policy design and to create a mandate of sorts for what they are doing. Consider some program domains such as welfare-to-work, and construe all the 'implementers,' from the Secretary of Health and Human Services through the state and county senior managers down to the lowest-level case workers as a sort of network through which ideas and effort can flow and can become organized. These ideas concern both policy design and the choice of implementation instruments. From the mid-1980s through the mid-1990s this network produced a good deal of lore, and a bit of experimental evidence, that a more work-oriented welfare policy might be effective and would not be unduly harmful to the poor. Counter-claims were also produced. But in the end, the experience of many implementers combined with conservative Republican political leadership and very widespread support in public opinion created the federal welfare reform legislation of 1996. The preferred implementation instruments were a high degree of devolution to the states with regard to means but rather sharp financial incentives to compel adherence to federal government objectives. Deficiencies in the legislation will no doubt be brought to light in the course of implementation and further change will occur.

In some sense, then, 'the policy system is learning,' or 'evolving,' and the implementation process is a part of that system (Goggin et al., 1990; Majone and Wildavsky, 1979). To be sure, 'learning' and 'evolving' are implicitly favorable ways to characterize a policy change. Many observers would object to this characterization of welfare reform. But eschewing value-laden language altogether would denature a phenomenon like implementation, which is so intimately connected to democratic policy choice and to the challenges of creating public value for the citizenry.

Abstract

Implementation science has developed rapidly and has established frameworks for summarizing a variety of influences on intended outcomes. The frameworks are useful for guiding the work of implementation in typical human service practice settings and for generating useful hypotheses for social sciences to explore. Evaluations of successful efforts to make full and effective use of social science innovations to benefit citizens and society have led to rapid expansion of implementation science.

Implementation Defined

> Implementation is defined as a specified set of activities designed to put into practice an activity or program of known dimensions. According to this definition, implementation processes are purposeful and are described in sufficient detail such that independent observers can detect the presence and strength of the 'specific set of activities' related to implementation. In addition, the activity or program being implemented is described in sufficient detail so that independent observers can detect its presence and strength. When thinking about implementation the observer must be aware of two sets of activities (intervention-level activity and implementation-level activity) and two sets of outcomes (intervention outcomes and implementation outcomes).
>
> Fixsen et al., 2005, p. 5

Implementation is universal and applies to any attempt to use innovations in practice. The implementation activities designed to put into practice an activity or program may be haphazard and unintentional (do the best you can), or they can be purposeful and specified well (do what is most effective). Using well-specified implementation supports has a substantial impact on intervention outcomes in practice. Active implementation frameworks help define effective implementation supports and are outlined in this article.

Innovation Defined

Implementation is in service to a well-defined innovation. An innovation is anything new to an individual, organization, or human service system (Rogers, 1995). The innovation may be a therapeutic intervention, instruction method, evaluation practice, management practice, clinical guideline, policy directive, improvement initiative, or other activity or program.

As noted in the definition of implementation quoted above, the extent to which an innovation is operationalized affects the ability to use the intervention in practice. Usable innovation criteria are outlined in this article.

Human Services Defined

The phrase human services is used to denote the full spectrum of services where one human being (e.g., a therapist; teacher; community organizer) is interacting with another human being (e.g., a student; neighborhood resident) in a way that is intended to be helpful. Human service domains include child welfare, community development, corrections, education, health, global health, mental health, public health, social services, substance abuse treatment, and others. Literature and examples drawn from human services are used in this article along with examples from business, manufacturing, and computer science.

Rationale for Implementation Science

The interest in implementation has grown with the interest in evidence-based innovations. The evidence-based intervention movement began with the documentation of intervention and policy failures in human services. Eysenck (1952) was the first of many who reviewed a series of outcome studies and declared various therapies to be ineffective. Rittel and Webber (1973) and Van Meter and Van Horn (1975) were among those who summarized public policies designed to improve human services and noted their general lack of intended impact. These seminal reviews led to great debates and to a new focus on developing evidence-based (effective) approaches to human service interventions of all kinds.

As the evidence-based program movement has developed over the ensuing decades, it has become clear that innovations are not self-implementing in human services. Evidence-based practices and programs are celebrated when they are published. Disappointment follows when attempts generally fail to make use of them outside of experimental trials. This has become known as the science to service gap and the quality chasm (Institute of Medicine, 2001). Implementation is now recognized as the link between science and service and is studied in its own right. Evaluations of successful efforts to make full and effective use of innovations to benefit citizens and society have led to rapid expansion of implementation science.

Diffusion, Dissemination, and Implementation

Implementation science is a blend of three strands of knowledge development. First, diffusion theory as described by Rogers (1995) originated in the 1950s in agriculture and

focused on communication patterns related to adoption of innovations in farming (e.g., use of hybrid seed; crop rotation). Diffusion theory has been generalized to a wide variety of fields and is the best known of the three strands. The outcome of diffusion of information is a decision to adopt an innovation.

The second strand is dissemination theory or, more accurately, dissemination theories. Brownson et al. (2012) provide a summary of dissemination findings and Tabak et al. (2012) list over 60 theories pertaining primarily to dissemination. Dissemination theories typically focus on helping practitioners, managers, policy makers, and others understand research findings so they may be more likely to use those findings in their work. The outcome of dissemination is understanding an innovation and attempting to make use of the innovation in practice.

The third and most recent strand is implementation theory. Implementation theory is based on evaluations of attempts to use innovations in practice. Applied research data are accumulating rapidly as common language, common measures, and guiding frameworks become available. Meyers et al. (2012) provide a comparative summary of 25 implementation frameworks. The outcome of implementation is full, effective, and sustained use of an innovation in practice.

The field is on the verge of a unifying theory of implementation that includes diffusion and dissemination along with active approaches to moving science into service in order to realize the promise of evidence-based programs and other innovations.

Using Innovations in Practice

The evidence-based program movement has permeated all social sciences and human services in the past three decades. There is great appeal to the idea that governments and service agencies funded by governments should make use of innovations demonstrated to be effective. Why invest in using what does not work when effective (evidence-based) alternatives are available for use?

Problems arise because attempts to use innovations (evidence-based or otherwise) in typical service or living environments bring into play a variety of personal, organization, and system factors. Change stimulates concern and concern is a powerful inducement to maintain the comfort of the status quo, even when the evidence persistently demonstrates the need for change. In the United States, literacy outcomes for students have remained at a consistently modest level since 1971, hovering around a score of 215 on a 500-point scale for 9-year-old children. Thus, the fundamental elements of education instruction in school, district, state, and federal systems have maintained an unacceptable status quo in spite of decades of tremendous changes in policy, massive increases in funding, countless legislative mandates, huge investments in education science and technology, and the rise of compliance-oriented data systems.

These problems are noticeable because the pervasive growth of the evidence-based program movement globally has raised expectations for achieving socially significant outcomes in human services. The science to service gap has exposed the challenges related to fidelity, sustainability, and scalability. Implementation science has developed in part in response to these issues. Schofield (2004), Vernez et al. (2006), and others note that achieving socially significant outcomes on a useful scale will require scaling implementation supports needed to make use of effective innovations.

A Science of Implementation

The science of implementation has lagged behind the development of best practices in implementation. Logically, we cannot do research on purported effective implementation practices unless those practices are being used. Thus, the purposeful and active use of implementation best practices amounts to building a better laboratory in which research on implementation can be done. If we continue to use implementation practices that already have been studied and demonstrated to be insufficient, the best we can hope for is a replication of findings that show little or no effect. If we begin to use practices that are predicted to be effective by the active implementation frameworks, then we can hope for different (and perhaps improved) outcomes.

The active implementation frameworks (Fixsen et al., 2005; Blase et al., 2009) can be considered a mid-level theory of implementation (ICEBeRG, 2006). As such, the frameworks can provide guidance for action planning and the development of testable hypotheses to guide research. The active implementation frameworks fit the 14 dimensions described by Meyers et al. (2012) in their review of extant implementation frameworks, and incorporate many dimensions of diffusion and dissemination theories reviewed by Brownson et al. (2012) and Tabak et al. (2012).

The active implementation frameworks are based on the best available evidence. A thorough review and synthesis of transdisciplinary implementation evaluation articles was conducted, and the research base informed each component of the frameworks (Fixsen et al., 2005). The review of the literature has continued since 2005 and has resulted in modifications and additions to the frameworks (Blase et al., 2012; Fixsen et al., 2013). The active implementation components described in 2005 benefitted from systematic knowledge capture (using concept mapping and nominal group process; each an evidence-based approach to collecting qualitative data from groups) by experienced purveyors and users of a range of evidence-based programs (Blase et al., 2005), and by representatives of national racial, ethnic, family, and cultural advocacy groups (Blase and Fixsen, 2003). The information from these meetings expanded and operationalized best practices associated with the active implementation frameworks.

These methods comport with best practices in other fields for arriving at guidelines for clinical practice. Thus, the best available evidence and expert guidance in implementation science provide the foundations for the active implementation frameworks.

A Formula for Success

It is widely acknowledged that implementation science is complex and includes many influences operating simultaneously.

What is known about implementation science can be summarized in a formula for success that accounts for multiple levels of influence over time:

Effective Innovations × Effective Implementation × Enabling Contexts = Socially Significant Outcomes

To explain the formula for success, the following frameworks for implementation will be outlined in this article: (1) usable interventions, (2) implementation stages, (3) implementation drivers, (4) improvement cycles, (5) implementation teams, and (6) enabling contexts.

Effective Innovations: Usable Interventions

If the goal of innovations (evidence-based or otherwise) is to produce change, potential users need to know what the innovation is. Summaries of the literature since 1991 consistently point to the lack of specification of the independent variable (the innovation) in randomized control trials and other evaluations. Naleppa and Cagle (2010) provide a summary of the literature and of the methodological challenges related to this issue. From an implementation perspective, it is not enough for innovations to be 'evidence-based,' they also must be usable. Fixsen et al. (2013) described the criteria for interventions usable in practice.

1. Clear description of the innovation; philosophy, values, and principles; inclusion and exclusion criteria that define the population for which the innovation is intended.
2. Clear description of essential functions that must be present to say that an innovation exists in a given location (essential functions sometimes are referred to as core intervention components, active ingredients, or practice elements).
3. Operational definitions of the essential functions; the core activities that allow an innovation to be teachable, learnable, and doable in practice.
4. A practical assessment of the performance of practitioners who are using the innovation; the performance (fidelity) assessment is highly correlated with intended outcomes.

Innovations that meet these criteria are more likely to be teachable, learnable, doable, and assessable in practice. The evidence of effectiveness is established in criterion #4 that calls for continual assessment of the strength of the innovation as it is used in practice and continual assessment of intended outcomes. This requirement recognizes the complexity of human interactions and the mutual influences people exert on one another. It is expected that the use of innovations will vary within practitioners across time and experience, and across practitioners. To produce socially significant outcomes reliably, innovations need to be used within an acceptable range of performance.

When implementation difficulties are encountered, the lack of specification of an innovation is the first place to look for a solution. Vague ideas, general philosophies or principles, and statements of goals make it difficult for practitioners and others to know what to do in practice to realize the intended benefits. Innovations that meet the usable intervention criteria provide a strong foundation for teaching, learning, doing, and assessing innovations in practice.

Innovations are more than names and claims. In a compliance-oriented environment, it is tempting to simply say an innovation is being done in order to meet a requirement and pass a compliance review. For example, when new standards were issued for quality improvement in health care, many hospitals claimed they were using Total Quality Management (TQM) to meet these new requirements for accreditation. TQM is the application of complex Six Sigma and Lean Manufacturing principles and methods to health care. Westphal et al. (1997) conducted a study of 2721 hospitals and found that few of those that claimed using TQM actually used TQM as intended. The authors concluded, "If organizations can minimize evaluation and inspection of their internal operations by external constituents through adoption alone, they may neglect implementation altogether, decoupling operational routines from formally adopted programs" (p. 371).

In outcome-oriented environments, it is necessary to actually use the innovation in practice and show evidence that intended outcomes are being realized (fidelity of delivery, improvements for intended beneficiaries). Names and claims do not produce socially significant benefits.

Effective Implementation

Innovations (usable interventions) describe *what* to do but the evidence is overwhelming that knowing what to do is necessary but not sufficient for achieving socially significant outcomes (Kessler and Glasgow, 2011). The question is *how* to make use of innovations as intended in typical service settings outside the laboratory.

The status quo supports the existing ways of work. Innovations are, by definition, new ways of work for practitioners, organizations, and systems. Thus, practitioners must learn innovations, and organizations and systems must change to accommodate and support the new ways of work embodied in those innovations. Eventually, an innovation becomes the new standard way of work. After that, any new innovations must undergo the same process of changing the new status quo if they are to be effective and sustained. The process of change is never done as human service systems seek to continually improve socially significant outcomes. Implementation frameworks provide guidance for *how* to incorporate innovations into existing systems effectively and efficiently to realize socially significant outcomes.

Effective Implementation: Stages

The full and effective use of an innovation occurs over time. Stages of implementation have been identified. They are not linear although there are some time dimensions and sequences involved in the staged processes. The stages of implementation are exploration, installation, initial implementation, and full implementation.

During *exploration* information is exchanged and leads to a decision to attempt to use an innovation or not. Given the difficulties inherent in changing the status quo, an implementation team helps organizations and systems carefully consider the need for change, the availability of innovations

and implementation supports to fulfill the need, and the preparation of leadership for initiating and managing the change process over a few years. Convening groups of leaders, stakeholders, and partners is an important part of making the decision to implement an innovation. The understanding and support developed during the exploration stage helps organizations and practitioners negotiate the rocky shoals of change when later attempting to use innovations in complex human service environments. The availability of an implementation team ensures that the human resources are available to shepherd the innovation from an idea to full and effective use.

Installation preparations begin in earnest once a decision is made. Innovations typically have inclusion/exclusion criteria for participants and therefore affect referral processes. Supports for innovations also require extra resources for start-up, planning for training and coaching, and selecting staff who are ready and willing to try to make effective use of an innovation. Immediate impacts on organization and system functions, roles, and structures are considered and accommodations are agreed upon to help create a hospitable environment for practitioners to begin doing the new ways of work.

Some accumulation of resources (preparation of contracts, assignment of staff time) may begin during the exploration stage. During the installation stage, some resources promised during exploration may be difficult to obtain and may lead to further exploration work to bring more people to the table to have them be part of the innovation implementation process.

Implementation is a dynamic process and the stages are overlapping and nonlinear. Implementation teams are essential to expediting the process of exploration and anticipating the needs for installation stage resources. Lack of readiness and lack of resources frequently are found on lists of impediments to success. Experienced implementation teams can help focus attention, anticipate common issues, and avoid wasted time and effort during these early stages.

Initial implementation begins when the first newly trained practitioner attempts to use an innovation in his or her interactions with intended beneficiaries. Many attempts to use innovations fail at this point. As attempts commence to use an innovation in actual practice, the status quo is disturbed. When the use of an innovation requires changes in fundamental operations of an existing organization, the disturbance is more substantial and impacts the status quo more dramatically. Without engaged leadership and persistent implementation supports, the innovation likely will fail (Marzano et al., 2005; Nord and Tucker, 1987).

The availability of skilled implementation teams is important in each stage of implementation, and especially helpful for negotiating the multiple issues that arise during initial implementation. Given their expertise and experience, implementation team members anticipate reactions by the status quo and help organizations quickly change their standard operating methods to accommodate and support the innovation. If serious issues are encountered during initial implementation, it may require reengaging in exploration or installation stage activities to secure agreements or resources found lacking during the initial implementation attempt. The goal of an implementation team is to support the use the innovation as intended and to help overcome barriers to realizing the benefits of the innovation in each organization setting.

Full implementation is achieved when half or more of the intended users of an innovation are using it as intended (with fidelity). Without the support of a skilled implementation team, very few innovations reach full implementation. Estimates of 5–15% are common (Green, 2008; Vernez et al., 2006; Wiltsey Stirman et al., 2012). This means that few innovations such as evidence-based programs actually produce socially significant benefits in practice. Without implementation teams, efforts to support the use of innovations in various practice settings likely will be haphazard and reactive instead of purposeful and proactive.

Skilled implementation teams greatly improve the odds of producing higher rates of success (60–80%) in shorter periods of time (Saldana and Chamberlain, 2012). Implementation teams are not commonly available or purposely constituted in human services but are growing in number and sophistication as their value is recognized.

Effective Implementation: Drivers

Implementation drivers are the heart of the change processes that support the full, effective, and sustained use of innovations in complex human service environments.

In their review of the diffusion and dissemination literature, Greenhalgh et al. (2004) noted three categories of implementation-related activities: letting it happen, helping it happen, and making it happen. Letting it happen summarizes many attempts to use innovations that rely on diffusion of information through networks and communication patterns (e.g., publication of articles; conferences; champions). Others are helping it happen by providing ready access to useful summaries of the literature, Web sites aimed at practitioner and policy audiences, and persuasive communications in the form of social marketing. The idea is to get relevant information into the hands of those who could be using the innovation so they are better informed and more likely to find ways to use the innovation in their daily practice.

Letting it happen and helping it happen approaches result in about 5–15% use of innovations as intended. Making it happen approaches are quite different. They offer purposeful, active, and persistent supports for using innovations as intended and producing promised results in practice. Most of the 25 frameworks reviewed by Meyers et al. (2012), including the active implementation frameworks described in this article, fit the making it happen category.

A review of the implementation evaluation literature (Fixsen et al., 2005) found evidence in support of several factors that seem to drive full and effective uses of innovations. As shown in **Figure 1**, there are competency drivers, organization drivers, and leadership drivers associated with consistent use of innovations in typical human service settings and the production of intended benefits (Fixsen et al., 2009). As noted in the center of the triangle, the various components (e.g., coaching, facilitative administration) are integrated and focused on using the innovation as intended (e.g., fidelity). Furthermore, strengths in some components can be used purposefully to compensate for weaknesses in other components to still realize the goal of

Figure 1 Implementation drivers. Reproduced from Fixsen, D.L., Blase, K.A., Duda, M., Naoom, S.F., Van Dyke, M., June 2008. Establishing an infrastructure for implementing substance abuse programs. Invited presentations and workshop, OASAS, Albany, NY; used with permission.

producing use of the innovation as intended and therefore, reliable benefits. Again, the value of an implementation team is apparent to assure the use of implementation best practices to realize the intended benefits of innovations in typical human service settings.

The logic connecting implementation and innovations is clear in Figure 1. By definition, an innovation is new to practitioners and organizations. Thus, practitioners (and others) need to learn the new ways of work embodied in an innovation. Staff selection, training, coaching, and feedback from performance assessments frequently are cited in the literature as important ways to assure skilled use of innovations. Mentioned less often, but equally important, is the integration of these components. Too often practitioners leave training and find their new knowledge and skills are not supported by their supervisor ("that's not how we do things in my unit"). In an integrated approach, coaches (supervisors) are prepared to support and expand the knowledge and skills introduced in training.

Given the use of an innovation by practitioners, organizations need to change to accommodate and support the new ways of work if they are to be sustained. Creating a hospitable environment is the work of administrators who are alert for ways to change standard operating procedures to facilitate use of the innovation. It is also their task to remove impediments that are discovered as the innovation moves from initial implementation to full implementation. Facilitative administrators rely on data to inform their decisions as they seek to continually improve supports for practitioners and improve innovation outcomes. Given the multilevel impact of using innovations in existing systems, organizations need to help surrounding systems change to accommodate and facilitate the new ways of work (e.g., referrals, funding, accreditation, scheduling).

None of this will happen without engaged leadership (Marzano et al., 2005). Adaptive leadership is needed for solving difficult problems that arise when legitimate and competing interests collide (including wicked problems as defined by Rittel and Webber, 1973). For example, union interests to protect members from unnecessary intrusions in their workspace may conflict with requirements to conduct frequent performance (fidelity) assessments to assure use of an innovation. Adaptive issues require convening meetings to discover the issues underlying a problem, finding common ground with agreed upon outcomes, and arriving at consensus solutions that can be tried in practice and modified as needed to resolve the issue. Given the tentative identification of the problem and search for a solution, wicked problems requiring adaptive leadership often defy any permanent solution. They are said to be resolved at any point in time with the expectation that there will be an opportunity to resolve the problem again in the future.

Technical leadership is needed for managing daily operations of the organization, including assuring the operation of each of the implementation drivers at a high level or performance. These tame problems (Rittel and Webber, 1973) can be solved more readily since the problems are easier to identify, are agreed to be problematic, staff have the skills to solve them, and work groups can be formed and disbanded as needed to modify procedures, realize a solution, and establish the new methods as part of daily practice. Leaders need to engage in both technical and adaptive leadership skills. Applying technical leadership approaches to resolving adaptive issues can make the problems worse. Using adaptive leadership approaches to solve tame problems is inefficient. Implementation team members are alert to identifying the types of challenges they are facing and are involved in supporting the appropriate leadership strategies.

Effective Implementation: Improvement Cycles

In the early days of attempting to use evidence-based programs in typical practice settings, there was debate about the need to replicate an innovation exactly versus the need to adapt an innovation to local circumstances to achieve acceptance and use. There was also the notion that since an evidence-based innovation had research to support its effectiveness those results could be expected when employing it in practice. While these quaint ideas still have some currency in intellectual debates, the issues have been settled in practice: there is no such thing as exact replication, and no laboratory-developed innovation delivers in practice all the benefits one expects. In addition, the (sometimes wild) swings in combinations of public policy, funding, workforce availability, leadership, personal and family dynamics, and community values challenge even the most agile organizations to continue delivering excellent service with excellent outcomes in full implementation mode.

In implementation practice and science, innovations provide a place to begin. Reasonably so, evidence-based innovations offer higher expectations for good outcomes. Innovations that have been demonstrated to be effective and meet the usable intervention criteria have the practical information and supports needed to get started and then get better by using performance (fidelity) assessment and outcome data.

Adjustments and improvements are expected in the beginning and over time and are part of the continuing work of an implementation team.

Implementation teams make use of the plan, do, study, act (PDSA) improvement cycle designed to detect and correct errors and strengthen facilitators *en route* to realizing excellent outcomes. PDSA cycles sometimes are referred to as trial and learning cycles and fit well with the need to make changes in operations while preserving and improving intended outcomes. As used in implementation work, PDSA cycles take three forms (rapid-cycle, usability testing, practice-policy communication) that are distinguished by time frames (rapid, medium, longer term) and scope of issues (small, medium, large).

The first PDSA improvement cycles originally were used in manufacturing and business settings (Shewhart, 1939) and have since been employed in a wide variety of human service settings. Rapid-cycle uses of PDSA require frequent opportunities to do what was planned, study what has been done and the results, and make changes to improve the next plan. Note that rapid-cycle use of PDSA includes the assumption of clear accountability for achieving the desired outcomes. This is a good fit with the making it happen approach inherent in the active implementation frameworks. Rapid PDSA cycles are well suited to making improvements in teacher instruction behavior or therapist behavior from 1 day or week to the next. In these cases, plans can be adjusted and results known on a frequent basis and improvements can be made quickly. Implementation teams make use of rapid-cycle PDSA processes to develop usable interventions. Coaches make use of PDSA cycles as they work to expand the skills and improve the outcomes of practitioners.

Usability testing in human services is PDSA work with medium time frames and issues with more interactive components. Usability testing is done with iterative groups of four or five individuals (Akin et al., 2013; Genov, 2005). For innovation development or capacity building, the number of iterations equals the opportunities to learn, adjust, and learn again. For example, assume 20 people need to be trained and training capacity needs to be developed. Capacity to do training well means having skilled trainers who:

- know the material well,
- can deliver it effectively to adult learners,
- have established behavior rehearsal scenes,
- know how to carry out the behavior rehearsal leader and confederate roles so that trainees have the opportunity to practice essential skills (see usable intervention criteria), and
- have created useful pre-post training tests of knowledge and skill development.

If training is provided to all 20 people at one time, there is one opportunity to develop training capacity and any lessons learned have to wait until next time. If the focus broadens from not only training 20 people but also to developing effective and durable training capacity, then training is done with iterative groups of four or five people. The usability testing format provides more opportunities for the trainers to build their capacity (plan training materials, do training, see the pre-post results, make changes for improved training materials and methods, do it again), while still providing training for all 20 people. The difference is substantial when developing usable interventions and establishing effective implementation supports.

Practice–policy communication cycles are another example of the application of PDSA logic in human services (Fixsen et al., 2013). For example, implementation team members report monthly to the executive managers regarding the systemic facilitators for and barriers to achieving and sustaining excellent outcomes. The implementation team is highly involved in reality at the practice level, can use their first-hand knowledge and data to describe to policy makers what is working or not, and can offer suggestions for how to change roles, functions, and structures in the organization/system to support improved outcomes. Based on this information, policy makers and executive leaders have the authority to make changes to facilitate the full, effective, and sustained use of innovations to achieve socially significant outcomes. Iterative use of such feedback and problem-solving loops can result in a transformed organization or system that is increasingly designed to support effective interventions and effective implementation. It has become an enabling context for supporting the innovation and realizing excellent outcomes.

The use of improvement cycles in implementation work is as important as implementation drivers or stages. Every attempt to do something is an opportunity to learn how to do it better next time. Many people plan and do. Few study and act, and fewer yet use improvement cycles on purpose and persist until they realize intended outcomes.

Effective Implementation: Implementation Teams

Implementation teams are essential to full, effective, and sustained use of innovations. They are *who* do the work of implementation. Like surgical teams, sports teams, financial accounting teams, and others, implementation team members work together to achieve intended outcomes – innovation outcomes and implementation outcomes – in spite of the complexities faced in practice. The functions of implementation teams have been noted throughout this article. In summary, implementation team members are experts in the processes to establish usable innovations, know and contribute to the science of implementation, and participate in organization and system change processes to develop enabling contexts for effective innovations and effective implementation (see the formula for success). Implementation teams greatly increase the likelihood of successful use of innovations and shorten the time for reaching full implementation (Fixsen et al., 2005; Nord and Tucker, 1987; Saldana and Chamberlain, 2012).

Enabling Contexts: Creating Hospitable Environments

It is a truism that all organizations and systems are perfectly designed to achieve exactly the results they obtain ("If you do what you've always done …"). This statement does not impute intention to the design. Many organizations and systems are the accumulated product of decades of good ideas, leadership

plans, well-meaning reforms, and responses to political mandates and local needs. As noted in the formula for success, enabling contexts are needed to achieve and sustain socially significant outcomes. Effective innovations and effective implementation methods interact with the context. Thus, the context needs to change to facilitate the work of innovation practitioners and implementation teams if new (and improved) results are to be realized and sustained.

The process of creating enabling contexts is complex and involves a broad view of interactions among organization and system components within and between multiple layers. Fundamental to enabling contexts is the use of knowledge. Kenneth Arrow (1963) won the Nobel Prize for introducing the idea of information economics. The premise is that knowledge-based activities gain in value with use, unlike atom-based resources that are depleted with use. Thus, knowledge-based organizations and systems make use of information to enable the work in increasingly precise and flexible ways that in turn produce more and better information for ongoing improvements. One glance at the amazing progress of digital products and information systems over the past five decades gives credence to Arrow's premise.

Not every organization enables knowledge-based solutions; if that were the case, every organization would be performing at peak effectiveness and efficiency. According to Von Krogh et al. (2000), intended outcomes can be amplified by designing enabling contexts that purposefully:

- grapple with unique cultural and interpersonal conditions,
- dismantle as many individual and organizational barriers as possible (organization structures can facilitate or hinder enabling interactions within the organization),
- share tacit knowledge with microcommunities (such as implementation teams),
- align contexts, strategies, and structures.

They state that traditional organizations and systems can no longer coordinate activities "in a world where boundaries are fuzzy, relationships are ever more complex, and the competitive environment is in constant flux" (p. 177).

Other contributions come from complexity theory. Complexity theory is useful for understanding how even loosely interrelated components of systems can influence one another as they interact, and how small changes in a few parts of a system can result in massive changes in system functions and outcomes. The practice–policy communication cycle is built on complexity theory and relies on implementation teams to convey meaningful information and act on that information within a human service system (Fixsen et al., 2013). It provides a venue where "thinking can be challenged, issues about authority and the exercise of power candidly explored, and where participants can continue to learn and adapt to ever-changing circumstances" (Onyett et al., 2009, p. 3). For implementation work designed to use innovations at scale, the improvement cycles are essential for quickly finding solutions to thorny problems that inevitably arise in organization and system contexts.

The implementation field has developed well enough to begin research on these challenges. A longitudinal study of organizations that are attempting to use evidence-based programs provides a view of the factors influencing initial adoption, deadoption, readoption, and full implementation of innovations (Panzano et al., 2004). Recently, Glisson et al. (2010) carried out a seminal study of interactions among layers of services, organizations, and systems. This study combined an evidence-based approach to service delivery and an evidence-based approach to system change in a 2×2 experimental design where US counties were randomized to conditions. The results showed that each intervention was effective when used alone. However, the best outcomes for youths resulted when the interventions were combined, that is, when the evidence-based service was operating in a changed system.

The Glisson et al. (2010) experiment is the first to combine simultaneously the three components of the formula for success – evidence-based innovations supported by skilled implementation teams in contexts that were more or less enabling. Socially significant outcomes were the result of attention to each component. Note that the study would not have been possible to conduct in the absence of skilled implementation teams who were well prepared to produce high-fidelity examples of each evidence-based intervention. This study is a good example of how implementation done well in practice creates a better laboratory in which to study implementation variables.

The lack of implementation teams and implementation expertise is a major impediment to realizing goals in human service systems (Schofield, 2004). Human behavior is complex, interactions among humans add to the complexity, and provider organizations and systems often lack the information and skills needed to make meaningful change. Human service systems simultaneously are ever changing and intractable. Improved practices to initiate and mange change and conduct research on system change is the next great frontier in implementation science.

Conclusion

Implementation science is a new science and is reaching a point of geometric growth. Implementation frameworks provide guidance for implementation practice, and improved practice provides a better laboratory for studying implementation done well. This creates a virtuous cycle that feeds on itself to rapidly develop better practices and better science. The value of virtuous cycles is seen in the last century in the computer industry where crude silicone-based integrated circuits were used to develop and manufacture more effective and efficient integrated circuits. Those improved versions then were used to create the next generation of even better integrated circuits. Implementation science is on the verge of following this path with the development of active implementation frameworks to guide the next generation of improved frameworks.

The long-time frames for implementation slow the process of discovery and improvement. Thus, there is a premium on using improvement cycles on purpose, recording data at each point of the journey, and improving the efficiency of the process as well as its effectiveness. The complexity and long-time frames inherent in implementation present challenges related to measures, research designs, and theory development. The transdisciplinary involvement in implementation makes language and conceptual thinking difficult and frustrates efforts

to find and summarize the literature(s). Nevertheless, implementation science has come a long way and is on the brink of advancing rapidly in the coming decades.

Implicit Association Test

Sarah Teige-Mocigemba and Karl Christoph Klauer, University of Freiburg, Freiburg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Implicit Association Test (IAT) is one of the most often used indirect measures of attitudes, stereotypes, or personality traits in psychology. It is indirect in that participants are not asked to report on their attitudes, stereotypes, or dispositions. Instead, this information is inferred from participants' performance in the IAT. We review the IAT's psychometric properties in terms of reliability and validity. Theories accounting for IAT effects are briefly discussed. Different approaches to deal with confounding influences on IAT effects are considered.

The Implicit Association Test (IAT) was first proposed in 1998 by Anthony Greenwald and colleagues (Greenwald et al., 1998). It is a categorization task that provides a flexible framework within which indirect measures of attitudes, stereotypes, and diverse behavioral dispositions can be designed. The measures are indirect in the sense that participants undergoing an IAT are not asked to report on their attitudes, stereotypes, or dispositions. Instead, they are asked to work as fast and accurately as possible on the categorization task, and attitudes, stereotypes, or dispositions are inferred from their performance in the task. Even when participants may suspect that attitudes, stereotypes, or dispositions are to be measured, it is not immediately obvious to them how task performance is used to assess these variables. Indirect measures thereby aim at overcoming important limitations of direct measures such as self-reports, in particular the susceptibility to self-presentational distortions (e.g., social desirable responding) and introspective limits (e.g., Nisbett and Wilson, 1977). In contrast to most other indirect measures, the IAT measures were found to exhibit satisfactory reliability estimates when reliability is assessed in terms of the internal consistency of the measure. This and the procedure's flexibility promoted the widespread use of the IAT in diverse psychological research domains.

This article is organized as follows: first, we describe the IAT procedure. This is followed by a review of the IAT's psychometric properties in terms of reliability and validity. Theories accounting for IAT effects are then briefly discussed along with mathematical process models based on these theories. Finally, different approaches on how to deal with confounding influences on IAT effects are considered.

Procedure

The IAT requires participants to assign stimuli of four categories, two target categories (e.g., Black vs White) and two attribute categories (e.g., negative vs positive), as fast and accurately as possible to two response keys. A typical IAT consists of seven blocks (for details, see **Table 1**), three of which are practice blocks acquainting participants with the categorization rules, the target stimuli (e.g., portraits of Blacks vs Whites), and the attribute stimuli (e.g., negative vs positive adjectives). In the remaining diagnostically relevant test blocks, participants are to categorize stimuli of all four categories, using only two response keys. The typical finding is that participants respond faster and more accurately, when two overlapping categories share one response (e.g., Black and negative vs White and positive for a prejudiced person) than when two categories with little overlap share one response (e.g., Black and positive vs White and negative for a prejudiced person). This performance difference between the two differently combined categorization tasks is reflected in the IAT effect, which is interpreted as revealing size and direction of the association strength between target categories and attribute categories.

Table 1 Example of a racial attitude Implicit Association Test: task sequence and recommended implementation details

Task sequence				
			Response key assignment	
Block	N *of trials*	*Task*	*Left key*	*Right key*
1	20	Target discrimination	Black	White
2	20	Attribute discrimination	Negative	Positive
3	20	Initial combined task	Black, negative	White, positive
4	40	Initial combined task	Black, negative	White, positive
5	20 or 40	Reversed target discrimination	White	Black
6	20	Reversed combined task	White, negative	Black, positive
7	40	Reversed combined task	White, negative	Black, positive

Recommended implementation details	
Instruction	Respond as fast and accurately as possible!
Correction of errors	Required, error cue: red 'X' or 'error' below stimulus
Category labels	Displayed in the corresponding upper screen corners
Intertrial interval	150 ms–750 ms (most often used: 250 ms)
Number of stimuli	Five to six per category (at least two)
Trial order in combined blocks	Alternation between target and attribute stimuli, otherwise randomized if group differences are the main focus of the experiment, but fixed for all participants in correlational studies

Note: Nosek et al. (2007) recommended increasing the number of trials in the fifth block as an effective means to reduce order effects of the combined tasks (see the section Handling Confounding Influences on the IAT Effect). Therefore, some IAT procedures present 40 instead of 20 trials in the block, in which participants practice the reversed target discrimination task.

For example, if performance is faster and more accurate in the Black/negative–White/positive block (mapping 'Black' and 'negative' on one key and 'White' and 'positive' on the other key) than in the White/negative–Black/positive block (mapping 'White' and 'negative' on one key and 'Black' and 'positive' on the other key), then this is considered to indicate the existence of implicit racial preferences favoring Whites over Blacks. The IAT effect is thus a relative measure: A racial attitude IAT, for example, provides only information about an individual's preference for one category over the other (e.g., a preference for Whites over Blacks or vice versa). In contrast, conclusions about an individual's evaluation of a single category (e.g., Blacks) cannot be derived (for a review of indirect measures that allow for the assessment of single categories, see Teige-Mocigemba et al., 2010).

For the implementation of IATs (for details, see **Table 1**), software packages such as E-Prime, Inquisit, and Direct-RT, among others, can be used and sample programs are available on the Internet (see list of Relevant Websites). Among the many scoring procedures that can be found in the literature, the so-called conventional IAT score and the so-called *D* measures are used most often to calculate IAT effects (for details, see Greenwald et al., 2003). The conventional IAT score is based on the difference between log-transformed, correct response latencies of the two combined tasks (e.g., sixth and seventh blocks minus third and fourth blocks in **Table 1**), with latencies smaller than 300 ms or greater than 3000 ms being recoded to 300 ms and 3000 ms, respectively. For descriptive statistics, however, IAT scores based on raw response latencies are often reported.

The *D* measures, on the other hand, use modified upper and lower tail treatment of latencies, include latencies of both correct and incorrect responses (with the latter being increased by an error penalty), and apply an individual standardization similar to that in Cohen's effect size measure *d*. Due to the ongoing discussion about which scoring algorithm is to be preferred (e.g., Wentura and Rothermund, 2007), many researchers report analyses based on both algorithms.

Psychometric Properties of the IAT

Reliability

To date, only few indirect measures reach the reliability levels that have been repeatedly found for the IAT. Split-half reliabilities and internal consistencies (Cronbach's alpha) of IAT effects typically range from .70–.90 with slight differences depending on the method of calculation (Nosek et al., 2007). The IAT's test–retest reliability, on the other hand, reaches less satisfactory levels of .25–.69 (mean and medium estimates of about .50; Lane et al., 2007) with little variation as a function of the retest interval. This discrepancy between satisfactory internal consistency and unsatisfactory test–retest reliability has been attributed to the impact of context effects on IAT scores (e.g., Blair, 2002). Such context effects might indicate the IAT's sensitivity to changes in the construct of interest (i.e., IAT as a state measure) and/or the IAT's susceptibility to changes in additional sources of variance not related to the construct to be measured (i.e., IAT as an insufficiently reliable trait measure) such as test taking strategies, learning effects, or other component response processes that do not reflect associations, per se. We come back to such contaminants of IAT effects below.

Validity

Group Level

Evidence for the IAT's validity comes from experiments at the group level and studies at the individual level. At the group level, firstly, the IAT has been shown to reflect universal attitudes for which the direction can be assumed on a priori grounds (e.g., a preference for flowers over insects, Greenwald et al., 1998). Secondly, the IAT has been shown to reflect to-be-expected differences between specific groups. For example, homosexuals and heterosexuals differed in their homosexuality attitude IAT effects (Banse et al., 2001), and White and Black participants differed in their racial attitude IAT effects (Nosek et al., 2002). Groups differing with regard to stigmatized behavior, on the other hand, were not consistently distinguished by an IAT (e.g., see Swanson et al., 2001). Thirdly, the IAT has been shown to reflect newly formed attitudes (Olson and Fazio, 2001), indicating its ability to capture recently acquired preferences. In sum, the empirical evidence at the group level confirms the validity of the IAT. Note, however, that this (quasi)-experimental validation approach does not exclude the possibility that uncontrolled third variables account for the expected findings. For instance, instead of universal attitudes, specific characteristics of the selected stimulus sets may be responsible for the observed IAT effects (e.g., see Bluemke and Friese, 2006). Likewise, groups may differ not only with regard to the construct of interest (e.g., racial attitude), but also with regard to their cognitive abilities, which in turn might influence IAT effects (e.g., see Klauer et al., 2010).

Individual Level

At the individual level, firstly, the IAT has been shown to correlate with self-report measures with correlations ranging from about .24 (according to a meta-analysis of Hofmann et al., 2005) to .37 (according to a large-scale analysis of Nosek, 2005) with differences in correlations depending on the construct of interest (e.g., whether it addresses a socially sensitive domain or not), on the corresponding self-report measure (e.g., relative thermometer scale or questionnaire), and on the construct variability in the sample, among other influencing variables. These low-to-moderate correlations have been interpreted as evidence for the IAT's validity, although the to-be-expected size of indirect–direct correlations is still debated: Assuming that an IAT and a self-report measure tap the cognitive representation of one and the same construct in different ways, the IAT's correlations with self-report measures should be moderate to high (e.g., Nier, 2005). On the other hand, assuming that the IAT taps the cognitive representation of an 'implicit' construct that is independent of, or only weakly related to, the cognitive representation of an 'explicit' construct captured by self-report measures, the IAT's correlations with self-report measures should be low (e.g., Wilson et al., 2000).

In any event, at least the IAT's correlations with other indirect measures should be high because different indirect measures targeting the same construct should indeed tap the same, possibly implicit construct. Indirect–indirect correlations,

however, have been shown to be weak at best (e.g., Rudolph et al., 2008). These findings are often attributed to (1) insufficient reliability of indirect measures other than the IAT which limits indirect–indirect correlations (e.g., Teige et al., 2004) and/or (2) to structural misfit (i.e., different task demands) of indirect measures which has been shown to decrease correlations (see Payne et al., 2008).

Finally, the IAT has been shown to predict behavior over and above direct measures (e.g., Asendorpf et al., 2002). Particularly in socially sensitive domains such as prejudice, the IAT proved to be a better behavioral predictor than self-report measures, whereas it performed worse than self-report measures in domains that are less likely to be subject of self-presentational tendencies (Greenwald et al., 2009) or in health-related domains (e.g., Spruyt et al., 2007).

In sum, the empirical evidence at the individual level also confirms the validity of the IAT. As for the group level, however, uncontrolled third variables might in part account for the IAT's correlations with external criteria. For instance, as elaborated on below, cognitive abilities have been shown to contribute to the size of IAT effects (e.g., Klauer et al., 2010). Small, but significant correlations between IATs and behavior may thus not rely on interindividual differences in the construct of interest (e.g., aggressiveness), but on interindividual differences in cognitive skills that influence both an (e.g., aggressiveness) IAT and the likelihood to show a specific (e.g., aggressive) behavior. To assess the extent to which individual differences in IAT effects reflect variance due to confounded variables not related to the construct to be measured, it is helpful to gain an understanding of the psychological processes that shape the IAT effect and that permit confounded variables to exert their influences on IAT effects.

Process Models of the IAT

Stimulus–Response Compatibilities

De Houwer (2001, 2003) proposed that IAT effects rely on differences in stimulus–response compatibilities. According to this model, response keys acquire the meaning of the categories they are assigned to in the course of conducting an IAT (e.g., left key acquires negative meaning, right key acquires positive meaning). A presented IAT stimulus, on the other hand, is assumed to preactivate the response whose meaning is compatible with the stimulus features resulting in better performance, if the preactivated response is the correct response (i.e., facilitation), and in worse performance, if the preactivated response is the false response (i.e., response conflict). In a racial attitude IAT, for example, a prejudiced person should thus respond fast and accurately, if the categorization task requires pressing the negative key for a Black stimulus (i.e., stimulus–response compatibility). Conversely, the same prejudiced person should respond slow and less accurately, if the categorization task requires pressing the positive key for a Black stimulus (i.e., stimulus–response incompatibility). IAT effects are thus assumed to rely on differences of stimulus–response compatibilities between the test blocks (e.g., high stimulus–response compatibility for the Black/negative–White/positive block, low stimulus–response compatibility for the White/negative–Black/positive block for a prejudiced person).

Importantly, in De Houwer's account, not only may so-called 'relevant' stimulus features (i.e., construct-related features such as category membership) preactivate responses in an IAT, but also so-called 'irrelevant' stimulus features (i.e., features not related to the construct to be measured such as perceptual form). As discussed by De Houwer et al. (2005), this opens the door for a host of different variables to exert an influence on IAT effects because each and every feature according to which stimulus and response in an IAT can be compatible might impact on the IAT effect via stimulus–response compatibilities.

Random-Walk Processes

Brendl et al. (2001) proposed that IAT effects rely on differences in random-walk processes. According to this model, accumulation of stimulus information drives an internal counter toward one of two response thresholds. As soon as one response threshold is reached, the respective response is initiated (e.g., left or right key press). In an IAT, it is assumed that both information about target categories (such as category membership) and information about attribute categories (e.g., valence) drive the counter for each stimulus. If associated categories are assigned to one response key, the target information and the attribute information push the accumulation process in the same direction, resulting in fast and accurate performance. If, on the other hand, associated categories are assigned to different response keys, target and attribute information move the accumulation process in opposite directions, resulting in slower and less accurate performance.

For instance, if a Black stimulus is presented to a prejudiced person in the Black/negative–White/positive block, the information about category membership of the Black stimulus (i.e., a Black stimulus belongs to the category Black) and the information about valence of the Black stimulus (i.e., Black stimuli are negative for a prejudiced person) push the accumulation process toward the same response (i.e., to the Black/negative response key). In the White/negative–Black/positive block, on the other hand, category and valence information of the same Black stimulus move the accumulation process toward opposite responses, namely, to the (White/)negative key and to the Black(/positive) key. In most cases, information about category membership will have the stronger impact (i.e., responses will be correct in most trials). However, net accumulation rates of the test block with incompatible mapping will be lower than net accumulation rates of the test block with compatible mapping, leading to worse performance in the incompatible block. Such differences in net accumulation rates are thus assumed to contribute to performance differences between the two test blocks that constitute the IAT effect.

As a further process, Brendl et al. (2001) proposed that differences in response criteria contribute to the observed performance differences between test blocks: Because participants perceive the test block with incompatible mapping (referred to as incompatible block in the following) as more difficult than that with compatible mapping (referred to as compatible block in the following), they would adopt a more conservative response criterion in the incompatible block leading to slower responses. Brendl et al. further assumed that the first mechanism, different rates of information

accumulation, produces construct-related variance in the IAT effect, whereas the second mechanism, different speed-accuracy trade-offs mediated by different response criteria, constitutes a source of variance driven by strategic, situational, and/or trait-related influences on the IAT effect.

These assumptions were broadly confirmed by diffusion-model analyses of IAT data (Klauer et al., 2007). A diffusion model can be seen as an implementation of a random-walk model. The diffusion-model analysis allows one to decompose observed IAT effects into a component due to rates of information accumulation, tapping construct-related variance, and a component due to response criteria, tapping systematic variance due to speed-accuracy settings that is method-related (i.e., shared by IATs measuring different constructs), but not construct-related (i.e., does not covary with the to-be-measured variable).

Task-Switching Costs

Mierke and Klauer (2001, 2003) proposed that differences in task-switching costs contribute to IAT effects. Remember that a typical IAT task requires participants to apply either a target task (e.g., Does the presented stimulus belong to the category Black or White?) or an attribute task (e.g., Is the presented stimulus negative or positive?) depending on whether a target or an attribute stimulus is presented. In order to apply the correct task-set, participants thus have to switch between task-sets because target and attribute stimuli typically alternate from trial to trial. Task-set switching, however, is costly in that it requires time and cognitive resources. Any asymmetry of task-switching costs between the compatible and incompatible block may thus directly contribute to an IAT effect.

This is exactly what the task-switching account postulates. In the compatible block, it is possible to simplify the task, omitting many task-set switches, because in most cases it will be sufficient to apply the attribute task to both attribute and target stimuli. For instance, if a prejudiced person has to categorize a Black stimulus in the Black/negative–White/positive block, applying the attribute task (i.e., respond with 'negative') to the Black stimulus will lead to the same correct response as applying the target task (i.e., respond with 'Black') because the associated categories 'negative' and 'Black' are mapped onto the same response key. In the White/negative–Black/positive block, on the other hand, responding to a Black stimulus according to its valence will lead to an incorrect response. In the incompatible block, it is therefore required to identify and to apply the correct task-set in order to respond correctly. This asymmetry in the necessity of task-set switching implies that task-switching costs will be higher in the incompatible than in the compatible block. The differential task-switching costs thereby directly contribute to the IAT effect. Because there are interindividual differences in task-switching ability, the task-switching account also predicts a cognitive skill confound of IAT effects.

Note that in principle, the task-switching account allows for different confounded variables to exert an influence on IAT effects. This is because simplifying the IAT task in the compatible block is not necessarily based on the attribute dimension (e.g., valence), but can be based on any arbitrary feature shared by the attribute and the target stimuli. Accordingly, inasmuch as participants derive their responses in the compatible block from an arbitrary feature other than the attribute dimension, the IAT effect would reflect construct-unrelated rather than construct-related variance. Furthermore, the more participants tend to simplify the task in the compatible block, the higher is the to-be-expected contribution of individual differences in task-switching ability to IAT effects.

Figure-Ground Asymmetries

Rothermund and Wentura (2001, 2004) proposed that IAT effects rely on differences in the salience of stimulus categories. Similarly to the task-switching account, the figure-ground asymmetry account postulates that participants simplify the compatible block, but not the incompatible block of an IAT. In contrast to the task-switching account, however, it is assumed that the feature according to which participants categorize stimuli in simplifying the task is always salience. Specifically, Rothermund and Wentura argue that participants recode the attribute and the target tasks as figure-ground discriminations in the compatible block. For instance, negative stimuli should be more salient than positive stimuli because of the attention-grabbing power of negative information. Likewise, Black stimuli are assumed to be more salient than White stimuli because Black stimuli such as Black faces or names are less familiar (in Western societies). Accordingly, if the more salient stimuli (e.g., Black and negative stimuli) are to be mapped onto the same response key and the less salient stimuli onto the other as is the case in the compatible block, the complex 4-to-2 categorization task can be reduced to a binary figure-ground discrimination task of whether a presented stimulus belongs to the salient (i.e., figure) category or to the less salient (i.e., ground) category. Responses in the compatible block are therefore fast and accurate. If, however, the salient stimuli require different responses as is the case in the incompatible block, recoding the tasks as figure-ground discriminations cannot be used to simplify the task, leading to overall slower and less accurate responses. Figure-ground asymmetries, not valence associations, are thus assumed to constitute the size of IAT effects.

Note, however, that this does not exclude the possibility that the IAT effect comprises construct-related proportions of variance. That is, inasmuch as the valence of the target categories is a determinant of salience, salience may serve as a mediator between valence and IAT scores, thereby allowing for construct-related variance in IAT effects. For instance, inasmuch as Black stimuli are salient for a prejudiced person because they are negative (not because they belong to an unfamiliar category), the IAT effect may comprise construct-related proportions of variance.

Based on the idea that participants simplify the compatible block, Meissner and Rothermund (2013) have recently proposed a multinomial model, the ReAL model. The ReAL model uses the accuracy data of an IAT to disentangle an estimate for a component of the IAT effect that reflects simplifying processes and an estimate for a component mediated by residual associations that remain once the simplifying

processes have been factored out. Applying the model will, however, typically require the use of a modified IAT procedure.

The Quad Model

Like the diffusion model and the ReAL model, the Quad model (Conrey et al., 2005) aims to decompose observed IAT effects into different process components offering estimates of the contribution of these different processes. Specifically, the Quad model estimates (1) the ability to perform the separate categorization tasks and (2) the influence that associations between attributes and categories have on task performance, an influence that is additionally modulated by (3) the ability to overcome biased responses suggested by activated associations. Finally, the Quad model estimates (4) a guessing parameter that is assumed to drive responses in the absence of other information. Like the ReAL model, the Quad model is a multinomial model that uses only the accuracy data of the IAT. Unlike the ReAL model, it can be applied to the conventional IAT procedure. Both the ReAL and the Quad model require, however, a sufficient number of errors to be applicable.

Handling Confounding Influences on IAT Effects

The just reviewed process models suggest that the IAT effect is shaped by additional variables over and above the associations to be measured. Operating via different processes such variables include cognitive abilities (as predicted by the task-switching account), salience (as predicted by the figure-ground asymmetry account), and in fact any relevant or irrelevant feature that (1) allows for recoding the four categories of an IAT into two categories in the compatible IAT block (as predicted by the task-switching account), or that (2) generates a compatibility relation between stimuli and response keys (as predicted by the stimulus–response compatibility account). Finally, the random-walk account suggests an influence of the adoption of different response criteria for the compatible and incompatible blocks (i.e., differential speed-accuracy trade-off settings).

Indeed, there is evidence that cognitive abilities (e.g., Klauer et al., 2010), salience (e.g., Rothermund and Wentura, 2004), perceptual form (e.g., De Houwer et al., 2005), familiarity (e.g., Kinoshita and Peek-O'Leary, 2006), biased stimulus selections forcing redefinitions of the category labels (e.g., Govan and Williams, 2004), extrapersonal knowledge (cf Olson and Fazio, 2004), faking strategies (e.g., Röhner et al., 2011), and order of compatible and incompatible blocks (e.g., Nosek et al., 2007), among others (for a more detailed review, see Teige-Mocigemba et al., 2010) contribute to IAT effects.

In the absence of a comprehensive process model that takes all variables influencing an IAT effect into account, it is difficult to exactly determine the relative contribution of construct-related and confounding influences on the IAT effect. However, different methods exist to safeguard against the possibility that an observed effect or correlation reflects the operation of confounds instead of being caused by the construct to be measured. We will discuss four approaches that can be taken.

One method is to use the mathematical models just reviewed in the attempt to disentangle construct-related contributions from effects and correlations due to confounding factors as operationalized in each model. A second method is to obtain measures of confounding variables such as cognitive abilities or speed-accuracy trade-off settings using conventional regression analyses to attempt to control for their potential influence. A third method is to complement the IAT of interest with a maximally similar IAT that is, however, designed to measure an unrelated construct (R. Greifeneder, personal communication, 20 June 2013). For example, in addition to an IAT measuring racial prejudice (i.e., an IAT designed to measure the association between negative and Black and between positive and White), an IAT designed to measure the association between positive and persons with white shirts on the one hand and between negative and persons with black shirts on the other hand might be administered. Any effects or correlations that are shown by both these IATs would be attributed to confounded factors, whereas effects and correlations limited to the racial attitude IAT could be more safely attributed to an effect or correlation due to implicit racial preferences.

A final, related method would be to administer an alternative indirect measure designed to tap the same construct using different procedures (see Teige-Mocigemba et al., 2010; for a review). Inasmuch as the alternative measure and the IAT would share construct-related variance, but be less similar in terms of their susceptibility to the same confounding variables, effects and correlations shown by both dependent variables could be more safely attributed to the construct to be measured.

Conclusion

With the publication of the IAT 15 years ago, Greenwald and colleagues introduced a measure that became one of the most often used and most controversially discussed indirect measures. In this article, we have reviewed research on strengths and shortcomings of the IAT. Despite convincing evidence for the IAT's ability to reliably assess associations between categories (i.e., construct-related variance), several contaminants of IAT effects (i.e., systematic variance not related to the construct to be measured) have been revealed operating via different processes. Like any measure, the IAT is thus not process-pure and does not provide direct, undistorted access to associative structures. Instead, performance in the IAT is shaped by a conglomerate of different processes opening the door for different variables to influence IAT effects. Taking this into account, research using the IAT will certainly continue to play a central role in contributing to our understanding of human experience and behavior in a surprising diversity of domains.

Implicit Memory

Chad J Marsolek, University of Minnesota, Minneapolis, MN, USA

Abstract

Implicit memory is said to be operative when people do not deliberately or explicitly recollect information from the past yet they exhibit memory for a previous experience in an indirect manner. It has different properties compared with explicit memory, which is expressed when people consciously and deliberately recollect information from the past. The incremental theoretical progress in explaining implicit memory, especially one form of it labeled repetition priming, is summarized.

Introduction

Human memory is not unitary. This is dramatically evidenced by the phenomenon of medial temporal amnesia following brain damage or neurosurgery. In amnesia, some aspects of memory can be severely impaired while other aspects of memory remain relatively intact, and this has greatly impacted our understanding of human memory. The most famous case was that of the patient H.M. (Milner et al., 1968). Following surgical resection of the medial temporal lobes to relieve severe epilepsy, H.M. exhibited a severe impairment for forming new long-term memories of the sort that can be declared or put into words. Nevertheless, he retained the ability to hold information in short-term memory and to learn new skills of the sort that can be expressed through perceptual-motor tasks.

Testing of additional amnesic patients indicated that, even within the domain of long-term verbal memory, different forms of memory could be dissociated. Patients can be severely impaired in relatively direct memory tests like recall or recognition of previously presented words, yet they remain intact in their abilities to exhibit memory for words in more indirect ways (Warrington and Weiskrantz, 1970). For example, a common indirect memory test is word-stem completion, in which participants are given three-letter word beginnings that can be completed to form many common English words (e.g., TAB___). When asked to think of the first word completion that comes to mind for each stem, even severely amnesic patients produce words that were read previously (e.g., TABLE) at rates higher than that might be attributable to chance.

Subsequent testing of normal participants has uncovered additional ways in which direct and indirect memory performance can be experimentally dissociated. Following deep or meaningful encoding of one list of words (e.g., rating how much each word is liked) and shallow or nonmeaningful encoding of another list of words (e.g., comparing the vowels in one word with the vowels in the preceding word), the direct memory test of free recall indicates significantly greater memory for words that were deeply encoded than for words that were shallowly encoded. However, in the indirect memory test of word-stem completion, no difference is observed between those conditions (Graf et al., 1982). Another dissociation yields the opposite pattern of results. Following visual encoding of one list of words and auditory encoding of another list, the direct memory test of old/new recognition of visual words is little affected by whether the words were previously encoded visually or auditorily. However, the indirect memory test of visually identifying very briefly presented words indicates significantly greater performance for previously visually encoded words than for previously auditorily encoded words (Jacoby and Dallas, 1981). Such findings sparked great interest in what would later be termed as 'implicit memory.'

The terms 'implicit memory' and 'explicit memory' were put forward as descriptive concepts by Graf and Schacter in 1985, but the distinction was not particularly new. Schacter (1987) reviewed effects that fit the label of implicit memory, and some of the reviewed findings extend back to the 1800s. 'Explicit memory' is exhibited when participants consciously and deliberately attempt to recollect information from the past, such as in recall and recognition tests. Implicit memory is exhibited when participants do not deliberately attempt to recollect information from the past yet memory is still expressed in the performance of a task, such as word-stem completion. Roediger (2003) argued that this definition of implicit memory ultimately is too broad to be useful for the field of human memory. Assuming that memory can be defined as "after-effects of stimulation at one time that manifest themselves subsequently at a later time" (Tulving, 1983: p. 7), implicit memory would include all such manifestations that do not happen to involve deliberate recollection. The relatively unbounded nature of the term 'implicit memory' means that it would encompass too vast a set of diverse empirical observations (e.g., perhaps even including changes that occur in the immune system). In line with this concern, the present article focuses on 'long-term repetition priming' as the best-defined and best-studied example of 'implicit memory.' Long-term repetition priming refers to a facilitation in processing a stimulus due to previous processing of that stimulus or a highly similar one, such as in priming of word-stem completions (Tulving and Schacter, 1990). Although other phenomena such as 'short-term masked priming' (e.g., Forster and Davis, 1984) and 'semantic/associative priming' (e.g., Meyer and Schvaneveldt, 1976) may have some properties similar to those of long-term repetition priming, they also happen to have different properties and are not as such included in the focus of this article. During the last quarter century, incremental theoretical progress has been made in understanding long-term repetition priming and its dissociations with explicit memory.

Multiple Memory Systems Theory

The fundamental idea in the multiple memory systems perspective is that repetition priming and explicit memory rely on two different long-term memory stores (e.g., Squire, 1987). In other words, separate representations in separate memory systems exist to support repetition priming for an item and explicit memory for that item. The reason why depth of encoding of a word does not affect repetition priming for it but does affect explicit memory for it (Graf et al., 1982), and the reason why match of perceptual input modality (e.g., auditory and visual) between encoding and test affects repetition priming for an item but not explicit memory for an item (Jacoby and Dallas, 1981), is that separate memory systems support the two kinds of memory effect. The two systems have different representational properties, with one being affected by variables like depth of encoding and the other being affected by variables like perceptual input modality.

An initial suggestion was that repetition priming and explicit memory are supported by the procedural and declarative memory systems, respectively. The procedural memory system supports 'knowing how to do' things, and it involves memory contained in learned skills, cognitive operations, and perceptual abilities. The declarative memory system supports 'knowing that' as opposed to 'knowing how,' and it involves memory for information that can be declared or put into words (Cohen and Squire, 1980). Repetition priming typically involves enhancing perceptual abilities like visual word recognition, thus it may be supported by the procedural memory system. Explicit memory typically involves declaring what words were presented earlier in an experiment, thus it may be supported by the declarative memory system. Another suggestion was that the two effects are supported by the semantic and episodic memory systems, respectively. The semantic memory system stores general world knowledge of the sort that is shared among most people. The episodic memory system stores personal autobiographical memories, such as memories for personal events and experiences (Tulving, 1983). Because repetition priming typically is expressed through general abilities like word reading, it may be supported by the semantic memory system. Because explicit memory typically involves retrieving information from previous experiences in one's personal autobiographical history, it may be supported by the episodic memory system.

Single-System Processing Theory

The fundamental idea in the single-system processing perspective is that both repetition priming and explicit memory (and other forms of memory as well) are supported by a single undifferentiated memory system and the differences between them are that they engage different processes within the unified system (e.g., Roediger, 1990). To account for different patterns of results across repetition priming and explicit memory, appeals are made to the principle of transfer-appropriate processing. When the cognitive operations during encoding overlap with the cognitive operations during test, memory test performance is high. When the cognitive operations do not overlap well, memory test performance is low (Morris et al., 1977). By this theory, the reason why depth of encoding does not affect repetition priming but does affect explicit memory (Graf et al., 1982) is that repetition priming tests typically require only perceptually driven processing and not conceptually driven processing of the sort that matches deep encoding tasks, whereas explicit memory tests require conceptually driven processing of the sort that matches deep encoding tasks. The reason why match of perceptual input modality between encoding and test affects repetition priming but not explicit memory (Jacoby and Dallas, 1981) is that repetition priming tests typically require perceptually driven processes that may be modality-specific, whereas explicit memory tests require conceptually driven processing that is not modality-specific.

An Initial Resolution

A bit of a theoretical quandary ensued. Both the multiple memory systems theory and the single-system processing theory could account for the same functional dissociations between repetition priming and explicit memory. The main advantage for the multiple systems theory was that it more plausibly accounted for why amnesic patients are severely impaired in explicit memory but not in repetition priming. One system can be impaired independently of another. In addition, an appeal by single-system processing theorists to the idea that conceptually driven processing is selectively impaired in such patients was not convincing. Amnesic patients are capable of effective conceptually driven processing in situations other than testing of explicit memory. On the other hand, the main advantage for the single-system processing theory was that it avoided the problem that additional experimentation could inevitably lead to an 'explosion' of theorized memory systems. For example, when the priming test requires conceptually driven processing as opposed to typical priming tests that require only perceptually driven processing, Blaxton (1989) found that depth of encoding affects repetition priming, and Srinivas and Roediger (1990) found that perceptual-modality shifts between encoding and test do not affect repetition priming. Those results are opposite to those found when the priming test requires only perceptually driven processing (Graf et al., 1982; Jacoby and Dallas, 1981). Should such a pattern of results necessitate postulating yet another division of new memory systems? If so, an explosion of systems may cause theoretical chaos.

An initial resolution to the debate was developed by Schacter (1994). Functional dissociations between two memory effects are not sufficient to posit separate memory systems. Instead, additional dissociations from other methods and levels of analysis must provide independent but converging evidence for postulating separate memory systems (Schacter, 1992). From this perspective, Schacter (1994) hypothesized that most repetition priming effects are supported by the perceptual representation system (PRS). The PRS is a small collection of subsystems that are domain-specific and represent perceptual form information but not meaning-based or associative information. The PRS is functionally and neurally dissociable from the systems that underlie

explicit memory. Evidence for this distinction came from left and right cerebral hemispheric differences (Marsolek et al., 1992; Marsolek et al., 1996), complementary impaired and intact memory abilities following damage to different areas of the brain (e.g., Gabrieli et al., 1995), and neural activity in different areas of the brain as measured with functional neuroimaging (e.g., Schacter et al., 1996; Squire et al., 1992). The general understanding that repetition priming takes place within perceptual systems led several researchers to treat repetition priming (a memory effect) as a useful tool for testing the properties of perceptual systems (e.g., Biederman and Cooper, 1991; Bowers, 1996; Marsolek, 1999; Marsolek et al., 1992, 1996).

Bias Theory of Repetition Priming

An important aspect of the PRS theory is that repetition priming occurs when previous visual encoding of a word or object enhances the subsequent visual processing of that word or object at test. Previous visual encoding is purported to enhance the ability "to extract visual information from the test cue" (Schacter, 1994: p. 237). In other words, the previous perceptual encoding increases subsequent sensitivity or the ability to discriminate the test item from other possible items. An alternative to this perspective came from Ratcliff and McKoon (1996, 1997). They argued that repetition priming is not due to enhanced processing or increased sensitivity, but instead it is due to an increase in bias to make a response that corresponds to a previously processed item.

To support the bias theory, Ratcliff and McKoon (1996, 1997) used test tasks in which a word (e.g., 'lied') or a drawing of an object (e.g., a hot-air balloon) is flashed very briefly, and then two visually similar alternative words (e.g., 'lied' and 'died') or two visually similar alternative objects (e.g., a hot-air balloon or a typical light bulb) are presented. In a forced-choice test, participants must choose which of the two words or two objects had just been flashed. When the flashed item had been processed in a preceding task (e.g., 'lied' or hot-air balloon), identification of that item as the one that was flashed increased compared against a condition in which neither alternative had been processed in a preceding task. An additional finding was important for implicating bias as an explanation. When the nonflashed alternative item had been processed in a preceding task (e.g., 'died' or light bulb), identification of the flashed item (e.g., 'lied' or hot-air balloon) decreased compared against a condition in which neither alternative had been processed in a preceding task. In other words, there was a benefit in identifying the flashed item when it had been processed previously, and there was a cost in identifying the flashed item when the nonflashed item had been processed previously.

Ratcliff and McKoon (1996, 1997) developed models of word and object identification to account for these results in a concrete manner, one in which bias is implicated and not sensitivity. In these models, previous processing of an item does not enhance perceptual processing of that item at test. In particular, previous processing of an item does not increase the amount of diagnostic visual information that is extracted from the primed item during the forced-choice test. Instead, previous processing of an item increases the subsequent bias to interpret ambiguous perceptual information in a way that is consistent with the processing in a preceding task. In other words, previous processing of an item only increases a bias to make a subsequent choice that corresponds to that previous experience; it does not increase the subsequent ability to perceptually process or distinguish that item per se. By this explanation, when neither of the two alternatives in the forced-choice identification task had been processed in a preceding task, there is no difference in bias to report either item as the flashed item. However, when one of the alternatives had been processed in a preceding task, participants are biased to report that item as their response, whether or not it is the correct response.

Another finding in the initial research on bias effects turned out to be important (Ratcliff and McKoon, 1997). When both items in the forced-choice identification task (e.g., both 'lied' and 'died') had been processed in a preceding task, performance is equivalent to performance in the condition in which neither alternative had been primed. This was taken as evidence that in the both-primed condition the bias to respond with one alternative cancels out the bias to respond with the other alternative. However, subsequent research indicated that pattern of results is found only when high-frequency words are used. When low-frequency words are used, performance in the both-primed condition is greater than performance in the neither-primed condition (Bowers, 1999; Wagenmakers et al., 2000; Zeelenberg et al., 2002). This is a pattern of results that does not fit the original bias theory, because it indicates an increase in discrimination ability for both words in the both-primed condition that cannot be due to bias (the increased bias for each word should cancel each other out). Ratcliff and McKoon (2000) modified their initial model to account for the results obtained when low-frequency stimuli are used. The modifications enable both increased sensitivity and bias effects to play roles in repetition priming.

Cognitive Neuroscience Theory: Antipriming Accompanies Priming

Contemporary theory in cognitive neuroscience is taking advantage of the positive aspects of the foregoing theories – as well as integrating behavioral, neural, and neurocomputational evidence – to account for repetition priming (Marsolek, 2003). A notion adopted from the PRS theory is the importance of integrating evidence from multiple methods and multiple levels of analysis, to avoid theoretical ambiguity when considering only behavioral experimentation. A notion adopted from bias theory is that concrete models of the changes that take place in perceptual identification systems are crucial for understanding repetition priming (see also many of the chapters in Bowers and Marsolek, 2003). The general notion that previous experiences can have subsequent costs in addition to subsequent benefits also is adopted from the bias theory. Moreover, additional integrative evidence from the neural implementation of perceptual systems in neocortex and neurocomputational modeling of such systems enable a theory of repetition priming that can explain both

what it is and why it is (Marsolek, 2003). An important prediction from this theory is that antipriming is a phenomenon that should accompany observations of repetition priming.

The theory is strongly constrained by neuroscientific and neurocomputational evidence (Marsolek, 2008). The representations of different visual objects in neocortex are distributed and partially overlapping (Haxby et al., 2001; Tanaka, 2003), and they undergo learning-related changes after each time they are accessed and used to identify objects (Kobatake et al., 1998; Sigala and Logothetis, 2002). Neurocomputational models that simulate these properties in biologically plausible ways indicate that antipriming should accompany repetition priming (Marsolek et al., 2006). Antipriming occurs when a visual object representation is strengthened after it is used to identify an object (e.g., a piano), and the changes that take place also entail weakening of some other representations with which the strengthened representation overlaps (e.g., the representation for desk). Strengthening one visual object representation not only enhances the subsequent ability to identify that object (e.g., repetition priming for piano), but it also impairs the subsequent ability to identify some other objects (e.g., antipriming for desk), relative to a baseline condition in which objects are neither primed nor antiprimed. This pattern of results has been observed in young adults, amnesic patients, and their matched control participants (Marsolek et al., 2006).

By this theory, the integration of evidence from neural, functional, and computational levels of analysis (Marr, 1982) helps to explain why priming and antipriming take place (Marsolek, 2008). They both reflect a dynamic interplay of maintenance relearning of overlapping representations in visual object identification systems. Strengthening one representation entails weakening some others. When the previously weakened representations are used to successfully identify antiprimed objects, the strengthening of those objects' representations is of a greater than normal magnitude, helping to maintain them within a system of overlapping representations. This is evidenced by the finding that greater neural activity is elicited by antiprimed objects than by either primed objects or objects that are neither primed nor antiprimed. In addition, the timing of this activation difference is after objects are identified rather than during identification (Marsolek et al., 2010).

A Reconceptualization of Neuroimaging Effects

These recent results help to reconceptualize the neural repetition effect. This ubiquitous effect in neuroimaging is observed when a repeated stimulus elicits lower magnitude neural activity than a nonrepeated stimulus. The standard interpretation is that this reflects a decrease in activity due to habituation, sharpening of activity, or faster activations for the repeated stimuli (Grill-Spector et al., 2006). The reconceptualization is that nonrepeated stimuli are actually antiprimed stimuli, and antiprimed stimuli elicit an increase in activity that reflects a greater than normal magnitude of maintenance relearning (Marsolek et al., 2010).

The reconceptualization of the neural repetition effect is important. Traditionally, it has been understood as a neural correlate of the behavioral effect of repetition priming (Grill-Spector et al., 2006). By this understanding, the magnitude of the neural repetition effect for a participant should correlate with the magnitude of the behavioral repetition priming effect for that participant. However, in perceptual cortical areas (but not prefrontal areas), such correlations are not observed (Maccotta and Buckner, 2004; McMahon and Olson, 2007; Schacter et al., 2007; see also Dobbins et al., 2004). The reason may be that the neural repetition effect in perceptual areas is a marker of the magnitude of maintenance relearning after identifying an object rather than a marker of the improved processing of an object during identification (Marsolek et al., 2010). Future research is needed to more strongly test this possibility.

Abstract

This article describes the field of implicit social cognition. Mental association is introduced as a core concept that serves as the basis for the definition of several psychological constructs and the development of nonreactive, computerized measurement instruments designed to capture the automatic activation of mental associations. We further discuss the meaning of the term implicit and review research and theorizing on the relation between implicit and explicit measures; prediction of meaningful outcomes; and the formation, change, and contextualization of mental associations. The article concludes with a brief review of mathematical modeling in implicit social cognition and its impact on applied areas.

The term *implicit social cognition* refers to research in social psychology and related disciplines that uses a particular class of nonreactive, computerized measurement instruments to assess thoughts and feelings without directly asking participants to report on them (for a comprehensive review, see Gawronski and Payne, 2010). A central characteristic that distinguishes these tools from other kinds of unobtrusive measures is that they reduce participants' ability to strategically control their responses. These measures are often referred to as *implicit measures*, whereas traditional self-report measures are described as *explicit measures*.

Mental Association as a Core Concept

Based on the two central features of implicit measures, it is often claimed that they (1) overcome the well-known problems of socially desirable responding and (2) capture thoughts and feelings that are outside of conscious awareness, and thus inaccessible to self-report. Over the last few years, evidence conflicting with these assumptions has led many researchers to prefer more agnostic interpretations in terms of mental associations. Such interpretations are based on the idea that many important constructs of social cognition can be defined as associations between concepts in memory (Greenwald et al., 2002). For example, the construct of *attitude* has been defined as association between an object and a particular evaluation. Based on this definition, *prejudice* can be defined as evaluative associations involving a social group, and *self-esteem* as evaluative association involving the self. Similarly, *stereotypes* can be defined as semantic associations between a social group and stereotypical attributes, whereas the *self-concept* refers to semantic associations between the self and its attributes. In general, the concept of mental association is applicable to any kind of target objects (e.g., consumer products, political candidates) and their evaluative and semantic attributes. Although some theorists have proposed alternative frameworks that reject the notion of mental associations (Hughes et al., 2011), associative theorizing has been a driving force in the development of implicit measures and still serves as a conceptual core in research on implicit social cognition.

Measurement Procedures

Implicit measures are based on the idea that activation of a mental concept can spread to other associated concepts in memory. To the extent that the associative link between two concepts is sufficiently strong, spread of activation is assumed to occur automatically (i.e., unintentionally, unconsciously, efficiently, and uncontrollably). Implicit measures make use of such automatic processes by assessing the effect of stimuli or stimulus features on participants' performance (e.g., response times, error rates) in responding to other stimuli or stimulus features (for a review, see Gawronski and De Houwer, 2014).

Sequential Priming Tasks

The first type of implicit measures is based on the notion of sequential priming in cognitive psychology (for a review, see Wentura and Degner, 2010). In a typical sequential priming task, participants are briefly presented with a prime stimulus (e.g., a picture of a person) which is followed by a target stimulus. Participants' task is to categorize the target stimulus as quickly as possible into two alternative categories. Depending on the type of measure, participants may be asked to (1) classify the target stimulus as good or bad (i.e., *evaluative decision task*), (2) classify the target stimulus in terms of its semantic meaning (i.e., *semantic decision task*), or (3) decide whether the target stimulus is a meaningful word or a meaningless letter string (i.e., *lexical decision task*). The basic idea underlying sequential priming tasks is that responses to the target stimulus are facilitated (i.e., lower response times, higher accuracy) when it is preceded by a prime stimulus that is mentally associated with either the target stimulus itself (e.g., sequential priming with lexical decision tasks) or the feature that is relevant for categorization of the target stimulus (e.g., sequential priming with evaluative or semantic decision tasks). For example, using a variant of sequential priming involving evaluative target decisions, a person with negative associations toward Black people should be faster in responding to negative words and slower in responding to positive words when the target words are preceded by Black faces compared to neutral baseline primes (e.g., Fazio et al., 1995). Similarly, using a variant of sequential priming involving semantic target

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24066-X

decisions, a person with gender–stereotypical associations may be faster in responding to male and female pronouns after being presented with stereotype-congruent prime words (e.g., doctor-him, nurse-her) compared to stereotype-incongruent prime words (e.g., doctor-her, nurse-him) (e.g., Banaji and Hardin, 1996). Finally, using a variant of sequential priming involving lexical target decisions, a person may be faster in identifying certain adjectives (e.g., competent) as meaningful words after being exposed to a political candidate to the extent that this person has strong associations between the candidate and the attributes described by the target words (e.g., Wittenbrink et al., 1997).

Implicit Association Test

The implicit association test (IAT) consists of two binary categorization tasks that require participants to sort stimuli representing two opposing target concepts (e.g., Black and White faces) and stimuli representing two opposing attribute concepts (e.g., positive and negative words) as quickly as possible by pressing one of two response keys (Greenwald et al., 1998). The central assumption underlying the IAT is that fast and accurate responses will be facilitated when mentally associated concepts are mapped onto the same response key, and impaired when mentally associated concepts are mapped onto different keys. For example, to measure preferences for Whites over Blacks, participants might be asked to sort pictures of White and Black faces and words depicting pleasant and unpleasant objects. In one block of the task, participants may be asked to respond to White faces and positive words with one key and to Black faces and negative words with the other key. In another block of the task, participants may be asked to respond to Black faces and positive words with one key and to Whites faces and negative words with the other key. The relative difference in participants' performance (i.e., speed, accuracy) in the two blocks is typically interpreted as an index of participants' preference for Whites over Blacks, or vice versa. IAT scores are inherently relative (i.e., relative preference for one group over another), and the blocked presentation of association-congruent and association-incongruent trials has been linked to various sources of systematic measurement error. To overcome these limitations, researchers have developed a number of modified IAT variants that are amenable for assessing associations of a single target concept or a single attribute, and variants that avoid blocked presentations of association-congruent and association-incongruent trials (for a review, see Teige-Mocigemba et al., 2010).

Go/No-Go Association Task

In the go/no-go association task (GNAT; Nosek and Banaji, 2001), participants are asked to show a *go* response to different kinds of target stimuli (e.g., by pressing the space bar) and a *no-go* response to distracter stimuli (i.e., no button press). In one block of the task, the targets include stimuli related to the target concept of interest (e.g., Black faces) and stimuli related to one pole of a given attribute dimension (e.g., positive words); the distracters typically include stimuli related to the other pole of the attribute dimension (e.g., negative words). In a second block, the classification of the particular attribute poles as targets and distracters is reversed (e.g., *go* for Black faces and negative words, and *no-go* for positive words). GNAT trials typically include a response deadline such that participants are asked to show a *go* response to the targets before the expiration of that deadline. Error rates are analyzed by means of signal detection theory, such that differences in sensitivity scores (d′) between the two pairings of *go* trials (e.g., Black-positive vs. Black-negative) are interpreted as an index of associations between the target concept of interest and the respective attributes.

Extrinsic Affective Simon Task

In the Extrinsic Affective Simon task (EAST; De Houwer, 2003), participants are presented with colored words representing a target object and white words representing associated attributes. Participants are instructed to categorize the words in terms of their valence when they are shown in white, and to categorize them in terms of their color when they are colored. For example, in an EAST designed to measure evaluative associations of different kinds of beverages, participants may be presented with positive and negative words in white and with names of beverages that are presented in yellow on some trials and in blue on others. Participants' task is to press one key when they see either a white word of negative valence or a word printed in blue and to press another key when they see either a white word of positive valence or a word printed in yellow. To the extent that participants show faster (or more accurate) responses to a colored word (e.g., Coke) when the required response to this word is combined with a positive as compared to a negative response, it is inferred that participants have positive associations with the object depicted by the colored word (or vice versa). Although the EAST was originally designed as a measure of evaluative associations, a number of studies have demonstrated its applicability to semantic associations (e.g., Teige et al., 2004).

Affect Misattribution Procedure

The affect misattribution procedure (AMP; Payne et al., 2005) adopts the basic logic of sequential priming, in that it measures the effects of prime stimuli on responses to subsequently presented targets. However, the AMP differs from traditional variants of sequential priming by (1) using target stimuli that are ambiguous with regard to the target response and (2) relying on participants' actual judgments of the targets instead of speed or accuracy data. The basic idea underlying the AMP is that the prime stimuli activate thoughts and feelings that may be misattributed to the ambiguous target stimuli (Gawronski and Ye, 2014). For example, in an AMP to measure evaluative associations of racial groups, participants may be presented with Black and White faces as primes and neutral Chinese ideographs as targets. Participants' task is to indicate if they consider the Chinese ideograph as visually more pleasant or visually less pleasant than the average Chinese ideograph. The modal finding is that participants show more favorable responses to the Chinese ideographs when they were primed with a pleasant stimulus than when they are primed with an unpleasant stimulus. Such priming effects tend to emerge even

when participants receive detailed information about the operation of the task and are explicitly instructed to avoid any potential influence of the primes (Payne et al., 2005). Although the AMP has originally been designed to measure evaluative associations, modified variants of the task have been shown to be amenable for the measurement of semantic associations (e.g., Sava et al., 2012).

What Is 'Implicit' about Implicit Social Cognition?

A common source of confusion in implicit social cognition is the meaning of the term *implicit*. Whereas some researchers use the term to describe features of measurement procedures, others use it to describe features of psychological constructs (e.g., implicit attitudes). The first interpretation emerged from the goal of overcoming the effects of socially desirable responding on self-report measures (e.g., Fazio et al., 1995). Research in this tradition was inspired by earlier work in cognitive psychology investigating the role of voluntary and involuntary processes in attention (see Payne and Gawronski, 2010). The second interpretation emerged from the goal of capturing unconscious thoughts and feelings that are inaccessible to self-report (e.g., Greenwald and Banaji, 1995). Research in this tradition was inspired by earlier work on implicit memory, suggesting that prior experiences can influence performance on psychological tasks even when participants are unable to explicitly recall the relevant experience (see Payne and Gawronski, 2010).

Drawing on the notion of implicit memory, Greenwald and Banaji (1995) defined *implicit cognition* as "introspectively unidentified (or inaccurately identified) trace of past experience that mediates responses" (p. 5). Although this definition was meant to imply unawareness of the sources of mental contents, it has often been interpreted to imply unawareness of the mental contents themselves (e.g., unawareness of the source of an attitude vs. unawareness of the attitude itself). However, the latter interpretation conflicts with a considerable body of evidence, suggesting that the psychological constructs captured by nonreactive, computerized measures are consciously accessible and thus not unconscious (e.g., Hahn et al., 2014).

More recently, De Houwer et al. (2009) proposed an alternative conceptualization to overcome the common confusion regarding the meaning of the term implicit. According to this conceptualization, the terms *implicit* and *explicit* describe the processes by which a psychological attribute (e.g., attitude) influences measurement outcomes (which may be described as *measures* in the sense of measurement scores), rather than the procedure itself or the underlying attribute. Specifically, measurement outcomes may be described as *implicit* if the to-be-measured attribute influences participants' responses in an automatic fashion (e.g., unintentionally, uncontrollably). Conversely, measurement outcomes may be described as *explicit* if the to-be-measured attribute influences participants' responses in a controlled fashion (i.e., intentionally, controllably). Measurement procedures, on the other hand, may be described as *direct* if their measurement outcomes are based on participants' self-assessment of the to-be-measured attribute (e.g., when participants' racial attitudes are inferred from their self-reported liking of Black people). Conversely, measurement procedures may be described as *indirect* if their outcomes are not based on a self-assessment (e.g., when participants' racial attitudes are inferred from their reaction times to positive and negative words after being primed with Black faces) or when it is based on a self-assessment of attributes other than the to-be-measured attribute (e.g., when participants' racial attitudes are inferred from their self-reported liking of a neutral object after being primed with Black faces).

Relations between Implicit and Explicit Measures

In a meta-analysis on the IAT, Hofmann et al. (2005) found an average correlation of 0.24 between IAT scores and self-report measures. Similar findings have been reported by Cameron et al. (2012) for different procedures based on sequential priming. However, correlations in both meta-analyses varied considerably as a function of content domains as well as procedural and method-related factors. In general, implicit–explicit correlations tend to be higher when participants rely on intuitive, affective bases (e.g., feelings elicited by an object) as opposed to deliberate, cognitive bases (e.g., reasons for liking or disliking an object) when reporting an explicit judgment. Implicit and explicit measures also show higher correlations when they are similar in terms of their dimensionality (e.g., absolute evaluations of Blacks vs. relative preference for Whites over Blacks) and content (e.g., evaluations of affirmative action policies vs. evaluations of Black and White faces).

A variety of theories have been developed to explain variations in the relation between implicit and explicit measures. According to the MODE (*M*otivation and *O*pportunity and *DE*terminants) model (for a review, see Fazio, 2007), the relation between implicit and explicit measures depends on the motivation and opportunity to engage in effortful processing of judgment-relevant information. To the extent that people are motivated and have the opportunity to engage in effortful processing when making an explicit judgment, they are assumed to scrutinize the available information about the target object. In this case, correlations between implicit and explicit measures should be low. If, however, either the motivation or the opportunity to engage in effortful processing is low, people are assumed to rely on their automatically activated associations when making an explicit judgment. In this case, correlations between implicit and explicit measures should be high. These hypotheses are consistent with research showing that correlations between implicit and explicit measures of racial attitudes tend to be higher for participants low in motivation to control prejudiced reactions compared to participants high in motivation to control (e.g., Fazio et al., 1995). Other research supporting the MODE model includes studies showing that correlations between implicit and explicit measures tend to be higher when participants are asked to provide explicit judgments under time pressure than when they have unlimited time (e.g., Ranganath et al., 2008).

Another theory that explains varying correlations between implicit and explicit measures is the associative-propositional evaluation (APE) model (Gawronski and Bodenhausen, 2006). The APE model conceptualizes implicit and explicit evaluations as the behavioral outcomes of two qualitatively distinct – yet mutually interacting – mental processes. Whereas

implicit evaluations are assumed to be the outcome of associative processes, explicit evaluations are conceptualized as the outcome of propositional processes. Associative processes are further defined as the *activation* of mental associations on the basis of observed co-occurrences between stimuli in the environment and the similarity between features of environmental stimuli and existing representations. Propositional processes are defined as the *validation* of the information implied by activated associations on the basis of their consistency with other momentarily considered information. An important difference between the two processes is that associations may be activated regardless of whether a person considers these associations as a valid basis for an explicit judgment. According to the APE model, the central determinant of perceived validity is the consistency of the evaluation implied by activated associations with all other momentarily considered information. To the extent that this evaluation is consistent with other momentarily considered information, it may be regarded as valid and therefore used as a basis for an explicit judgment. If, however, the evaluation implied by activated associations is inconsistent with other momentarily considered information, the implied inconsistency may lead to a rejection of the implied evaluation as invalid. Whereas in the former case implicit and explicit measures are assumed to show corresponding evaluations, the two kinds of measures are assumed to show diverging evaluations in the latter case. Although the APE model shares many assumptions with the MODE model, an important aspect of the APE model is that effortful processing may not necessarily reduce the relation between implicit and explicit measures when the additionally considered information is consistent with the evaluation implied by activated associations. This assumption is supported by research showing that high motivation to control prejudiced reactions does not reduce the relation between implicit and explicit measures of racial prejudice when consistency can be restored in a way that does not imply a rejection of activated associations (e.g., by denying discrimination of the target group; see Gawronski et al., 2008).

Prediction

Implicit measures are often used as tools to predict meaningful psychological outcomes (e.g., behavior, decisions), and recent meta-analyses tend to support their predictive validity (e.g., Cameron et al., 2012; Greenwald et al., 2009). However, to justify the use of such resource-intensive tasks, many researchers have become concerned with unique aspects of behavior that are difficult to predict with explicit measures. According to Perugini et al. (2010), implicit measures may contribute to the prediction of outcomes over and above explicit measures in various ways, including (1) additive patterns, (2) double-dissociation patterns, (3) moderation patterns, and (4) interactive patterns.

Additive patterns involve cases in which implicit and explicit measures of the same construct jointly predict a particular outcome. Such cases tend to emerge when implicit measures are able to capture particular aspects of the outcome that are not captured by the explicit measure. Thus, additive patterns are best described in terms of explained variance, such that implicit measures may increase the total proportion of explained variance in the outcome measure compared to the variance that is explained by the explicit measure alone.

Although additive patterns have been obtained in a few studies, a more common finding is a double-dissociation in the prediction of different kinds of outcomes. In line with the assumptions of various dual-process theories (e.g., Fazio, 2007), implicit measures have been shown to outperform explicit measures in the prediction of spontaneous behavior, whereas explicit measures tend to outperform implicit measures in the prediction of deliberate behavior. For example, nonverbal behavior in interracial interactions typically shows stronger relations to implicit when compared to explicit measures, whereas verbal behavior has been shown to reveal stronger relations to explicit when compared to implicit measures (e.g., Dovidio et al., 2002).

Other research has focused on various moderators that determine whether a given outcome is predicted by implicit or explicit measures. Such moderating patterns have been shown for various situational factors and their individual difference counterparts (for a review, see Perugini et al., 2010). For example, implicit measures have shown stronger relations to eating behavior than explicit measures under conditions of cognitive depletion, whereas explicit measures showed stronger relations to eating behavior under control conditions (Hofmann et al., 2007). Correspondingly, implicit measures have been shown to outperform explicit measures in the prediction of eating behavior for people low in working memory capacity, whereas explicit measures outperformed implicit measures for people high in working memory capacity (Hofmann et al., 2008). Such findings are consistent with dual-process theories assuming that motivation and opportunity to engage in effortful processing are central moderators of the predictive validity of implicit and explicit measures (e.g., Fazio, 2007).

Deviating from approaches in which implicit and explicit measures are seen as competitors in the prediction of behavior, several studies have investigated interactive relations between the two kinds of measures. The general assumption underlying these studies is that discrepancies between implicit and explicit measures are indicative of an unpleasant psychological state that people aim to reduce. In line with this assumption, people showing large discrepancies between implicit and explicit measures of a particular psychological attribute (e.g., attitude, self-concept) have been shown to process discrepancy-related information more extensively than people with small discrepancies (e.g., Briñol et al., 2006). In a similar vein, combinations of high self-esteem on explicit measures and low self-esteem on implicit measures have been shown to predict various kinds of defensive behaviors (e.g., Jordan et al., 2003).

Formation, Change, and Context Effects

Several early theories of implicit social cognition assumed that implicit measures capture highly overlearned associations that have their roots in long-term socialization experiences (e.g., Wilson et al., 2000). Consistent with this assumption, several studies have shown that implicit measures are meaningfully related to early childhood experiences. However, although

long-term socialization experiences can be an important source of the associations captured by implicit measures, such experiences do not seem to be necessary. The latter conclusion is supported by research showing that recently formed associations that are based on minimal experiences can have a strong impact on implicit measures (e.g., Gregg et al., 2006). Resonating with the dual-process distinction of the APE model (Gawronski and Bodenhausen, 2006), these experiences may involve either descriptive information about a target object (i.e., propositional learning) or incidental pairings of a target object with other stimuli (i.e., associative learning). In the domain of attitudes, propositional learning plays a central role in research on persuasive communication, involving the processing of verbal arguments implying either a positive or negative evaluation of a given target object. Associative learning is prominently reflected in research on evaluative conditioning, which refers to the change in the evaluation of a formerly neutral conditioned stimulus due to its pairing with a positive or negative unconditioned stimulus. The currently available evidence suggests that implicit measures are able to capture newly formed associations regardless of whether they are product of associative or propositional learning (for a review, see Gawronski and Sritharan, 2010).

In addition to the question of how mental associations are formed, a central question is how existing associations can be changed. Several early studies suggested that, although associations captured by implicit measures can be formed relatively quickly as a result of minimal experiences, they seem to be much more resistant to change (e.g., Gregg et al., 2006). However, in contrast to this conclusion, a substantial body of research indicates that implicit measures of existing associations often show evidence for change even when explicit measures are unaffected (for a review, see Gawronski and Bodenhausen, 2006). According to the APE model, such patterns occur when repeated pairings of stimuli in the environment change the structure of associations in memory, and the information implied by the new association is rejected as a basis for an explicit judgment (e.g., Gawronski and LeBel, 2008). Moreover, the reverse pattern is predicted to occur when newly acquired information leads to a rejection of existing associations as a basis for an explicit judgment because of their inconsistency with the newly acquired information (e.g., Gawronski and Strack, 2004). Whereas the former case is assumed to produce changes on implicit but not explicit measures, the latter case is assumed to produce changes in explicit but not implicit measures. In addition, the APE model implies that implicit and explicit measures should show corresponding changes if (1) repeated pairings of stimuli in the environment change the structure of associations in memory and the information implied by the new association is accepted as a basis for an explicit judgment and (2) newly acquired descriptive information is accepted as valid and this information leads to formation of new associations in memory (e.g., Whitfield and Jordan, 2009).

Although implicit measures have been shown to be susceptible to various manipulations to induce long-lasting changes in underlying associations, some effects in the literature are more appropriately interpreted as reflecting temporary shifts that may dissipate over time. In Contrast to initial claims that implicit measures may be resistant to contextual influences, a considerable body of research has shown that they are in fact highly malleable (for a review, see Gawronski and Bodenhausen, 2006). For example, several studies have shown that the same target person can elicit different responses on implicit measures depending on the context in which the target is encountered (e.g., Wittenbrink et al., 2001). Such findings have fueled theoretical debates as to whether evaluations captured by implicit measures indeed reflect stable underlying representations (e.g., Fazio, 2007) or instead are constructed on the spot on the basis of momentarily accessible information (e.g., Schwarz, 2007). More recently, Gawronski et al. (2010) have proposed an integrative account that explains context effects by specifying the contextual conditions under which implicit measures reflect (1) initially acquired information, (2) subsequently acquired information that is inconsistent with the initial information, or (3) a mixture of both. According to their account, exposure to expectancy-violating information enhances attention to the context, which leads to an integration of the context into the newly formed representation of the expectancy-violating information. Thus, the expectancy-violating information is assumed to dominate responses only in the context in which this information has been acquired, whereas the previously acquired information is assumed to dominate responses in any other context. This account not only explains a wide range of context effects; it also includes several novel predictions about patterns of stability and change that have been empirically confirmed.

Lack of Process Purity

Implicit measures are often assumed to provide direct proxies for mental associations. However, although the impact of mental associations on implicit measures is rarely disputed in the field of implicit social cognition, a considerable body of research suggests that implicit measures do not provide process-pure reflections of mental associations. To disentangle the contribution of multiple, qualitatively distinct processes to implicit measures, several theorists have developed mathematical modeling procedures to quantify these processes, including applications of process dissociation, multinomial modeling, and diffusion modeling (for a review, see Sherman et al., 2010). The most prominent example is Conrey et al.'s (2005) quad model, which distinguishes between four qualitatively distinct processes underlying observed responses on implicit measures: (1) activation of an association; (2) detection of the correct response required by the task; (3) success at overcoming associative bias; and (4) guessing. Research using the quad model has provided more fine-grained insights into the mechanisms underlying previous findings obtained with implicit measures. Whereas some effects have been shown to be genuinely related to underlying associations, others stem from nonassociative processes, such as the ability to inhibit activated associations. For example, whereas extended training to associate racial groups with positive or negative attributes has been shown to influence associative bias, alcohol-related increases in implicit measures of racial bias stem from impaired inhibitory control rather than genuine changes in the underlying associations (for a review, see Sherman et al., 2008).

Applications

Although implicit measures have their origin in social psychology, they have been applied in virtually all areas of psychology (for an overview, see Gawronski and Payne, 2010). For example, a large body of research in clinical psychology has used implicit measures to investigate the processes underlying various psychopathologies and the effectiveness of different kinds of treatments (for a review, see Teachman et al., 2010). Similarly, research in health psychology has adopted implicit measures to gain deeper insights into the mechanisms underlying health-related behavior, including alcohol consumption, eating behavior, smoking, and sexual health behavior (for a review, see Wiers et al., 2010). Forensic psychologists have used implicit measures to study various psychopathologies in violent and sexual offenders as well as the determinants of recidivism (for a review, see Snowden and Gray, 2010). Research in consumer psychology has gained valuable insights from using implicit measures to study the determinants of product preferences and consumer choices (for a review, see Perkins and Forehand, 2010). Finally, research in political psychology has adopted implicit measures to study the sources of political preferences and determinants of voting decisions (for a review, see Gawronski et al., in press).

This article is a revision of the previous edition article by N. Christie, volume 11, pp. 7248–7251, © 2001, Elsevier Ltd.

Abstract

Although incarceration of prisoners is found worldwide, imprisonment rates and conditions vary dramatically. This article provides an overview of the general types, goals, and conditions of imprisonment. Variation in prison conditions and imprisonment rates are discussed along with the social causes of variation and the larger sociological effects of imprisonment.

Introduction

Imprisonment is generally understood to refer to involuntary or coerced physical confinement; however, imprisonment takes many different forms, and imprisonment rates vary significantly over time and geographical area. For instance, the United States of America, the world's imprisonment leader, incarcerates approximately 743 people per 100 000 inhabitants while over half of the countries and territories of the world imprison less than 150 (Walmsley, 2011). Variation in imprisonment rates is not simply a result of variation in crime rates; there are many different causes of variation, such as different goals of imprisonment, politics, and economics.

Types of Imprisonment

Although imprisonment is usually understood in the traditional sense of physical confinement of criminals, control can take many forms. Imprisonment in Western nations usually refers to confinement in small jail and prison cells; however, "Imprisonment is not only in small rooms. Whole societies, or segments of them, can experience the meaning of being in prison" (Christie, 2001: 2). For instance millions of people in open and closed Jewish ghettos during World War II and arguably in modern day North Korea (the Democratic People's Republic of Korea) experienced imprisonment despite formal incarceration in an official jail or prison. Outside of these extreme cases, millions of people worldwide are imprisoned in work camps, boot camps, or are confined to small sections of the community through house arrest, segregation, and/or GPS monitoring that will notify the police or probation officers if the prisoner strays outside of an authorized location.

Goals of Imprisonment

There are many reasons for and goals of imprisonment. From a criminological standpoint, imprisonment is used for retribution, deterrence, incapacitation, or rehabilitation. Retributive imprisonment is punishment that is considered morally just and deserved (i.e., 'just desserts'). Imprisonment of criminals can also prevent more crimes by incapacitating individual criminals while they are imprisoned and may deter future crimes by the incarcerated person (specific deterrence) or others who are made aware of criminals' imprisonment (general deterrence). Incarceration of criminals is also sometimes used as part of a rehabilitative or correctional treatment program aimed at altering prisoners' cognitive thinking, vocational skills, education, etc.

In addition to lowering crime rates or punishing criminals, imprisonment may have political and economic motives. Political leaders may incarcerate segments of the population who are considered 'undesirable' (e.g., economic, racial, ethnic, and religious minorities) in order to better manage and control them. For example, racial and ethnic minorities are disproportionately incarcerated, and minority population size is positively associated with imprisonment and sentencing disparities, presumably due to the dominant population viewing minorities as economic and political threats (Bridges and Crutchfield, 1988; Ulmer and Johnson, 2004; Blumer, 1958). Additionally, people who are unable to or refuse to participate in consumer society may be imprisoned (Bauman, 1998). Some prisoners are incarcerated as a result of state officials' attempts of quelling political movements. For instance, opposition leaders from Taiwan's movement for independence were imprisoned for challenging the standing regime, and thousands of African National Congress and Pan-African Congress members were imprisoned in South Africa for their efforts to end apartheid (Buntman and Huang, 2000).

Prisoners also have economic value. They are sometimes used as part of bribes and negotiations. Additionally, prisoners have historically been used as slave labor and as part of the war industry. For instance, prisoners of war were critical to the Germans and Soviets war efforts during World War II: "In their captured position, they are also prizes—they are here given a use function as a raw material for the control industry (Christie, 2000)" (as cited in Christie, 2001: 6). More recently, prisoners have become a commodity within the prison–industrial complex, particularly with the proliferation of private prisons.

Imprisonment Rates and Understanding Variance

In 2011, according to the International Centre for Prison Studies, 10.1 million people were incarcerated worldwide (Walmsley, 2011). Over half of those people were imprisoned in just three countries: the United States (2.29 million), China (1.65 million), and Russia (0.81 million). In order to account

for large variation in population size, imprisonment *rates* are more useful for comparative purposes. For instance, although China incarcerates twice as many people as Russia, because the Chinese population is much larger, Russia's incarceration rate it much greater (568 per 100 000 inhabitants) than China's (122 per 100 000). Approximately 146 per 100 000 of the world's population are incarcerated.

Countries that are otherwise similar can have very different incarceration rates. For instance, the United States of America incarcerates at a much higher rate (743 per 100 000 persons) than Canada (117 per 100 000) despite similar crime rates, culture, and economic structures and sharing a very long boarder (see Table 1). Similarly, Table 2 shows the great variation that exists between Eastern and Western European counties with former USSR nations, such as Russia and Georgia having much higher imprisonment rates. Imprisonment rates in Asia vary widely with much lower incarceration rates on the Indian subcontinent (42 per 100 000 average) compared to Eastern Asian nations (155.5 per 100 000 average) (see Table 3).

The great variation in imprisonment rates from nation to nation is not simply a reflection of variance in crime rates. Imprisonment rates may vary independently of crime rates due to changes in public sentiment, politics, law enforcement practices, and sentencing guidelines. For instance, the imprisonment rate in Russia decreased from 1400 per 100 000 in 1950 to 353 per 100 000 in 1989 and has since increased back up to 568 per 100 000. These changes were the result of changing politics – not a dramatic change in crime rates. Similarly, although Japan has a much lower imprisonment rate compared to other industrialized countries, its rate has grown over the past two decades due to longer sentences, an increase in the percent of one's sentence offenders must complete before release, and a decline in the parole rate (Shinkai, 2010). Finland and Germany both dramatically decreased their imprisonment rates intentionally by shifting from a reliance on imprisonment to punishments such as fines and community service (Weiss and MacKenzie, 2010). Paradigm shifts like these are the result of changing sentiment and policy.

The United States also underwent a paradigm shift during the same time frame; however, instead of lowering incarceration rates, the US increased the criminalization of drugs with the War on Drugs instead of treating drug use as a public health issue and despite relatively stable drug use rates. Conversely, many European nations, Canada, and Mexico, understand drug use to be a public health issue and have recently adopted public health focused harm-reduction measures in place of punishment. Decriminalization of all drugs in Portugal and heroin-assisted treatment programs around the world are related to

a decrease in violent and property crimes and, in turn, a decrease in incarceration of drug users (Greenwald, 2009; Loebermann and Verthein, 2009).

Prison Life

Prison life and conditions very considerably depending on the prison's location, goals, and classification and the community's perception of crime, criminals, and rights. Most prisons are 'closed,' total institutions that have power structures and social hierarchies unique from society outside of the prison walls (see Goffman 1961). Prisoners are under the control of guards with limited access to legal assistance and little recourse for living conditions or abuse. Prisoners, who are incarcerated for political or sexual crimes face the greatest abuses and harshest living conditions. Sex offenders in particular are at the bottom of prison hierarchy and are frequently victimized by guards and other prisoners alike.

Prisons are generally classified by the risk assessment of those housed within them and the fortification techniques used. Minimum and low security prisons are generally filled with inmates who are not consider violent or at great risk of escape attempts, medium security prisons house inmates who are considered moderate risks, and maximum security prisons are used to confine and closely control risky inmates. Some facilities, such as Category D prisons in England and Wales are 'open,' meaning that trusted prisoners may leave for home visits or employment. At the far extreme are Supermax prisons. These prisons are intended to house 'the worst of the worst' – those prisoners who are considered extremely dangerous to society in general or to other inmates and guards – and to 'break down all resistance' (Vervaet, 2010: 33). Inmates of Supermax prisons have no contact with other prisoners, are served food through a slot in the door, and are only allowed out of their cells for an hour a day. Isolation via solitary confinement – either due to incarceration in Supermax prisons, need for protection, or administrative punishment for violation of prison rules – is believed to cause social and psychological problems such as cognitive impairment, hallucinations and/or delusions, sensitivity to stimuli, depression, and anxiety (Haney, 2003).

Abuse and unsafe living conditions are rampant in prisons worldwide. Overcrowding, abuse, and health issues are common problems in prisons. Illness and diseases, such as HIV, hepatitis, and tuberculosis, are much more prevalent among inmates compared to the general population. Prison overcrowding prevents adequate sanitary conditions to be maintained and health care to be provided. Prisoners in Haiti the Ukraine must sleep in shifts because of overcrowding, and some prisoners in Eritrea are housed in unventilated storage containers and basements because regular prisons are over capacity (Bureau of Democracy, Human Rights and Labor, 2013). California prisons are operating at 180% capacity resulting in approximately 34 000 more inmates being housed in California prisons than the facilities are designed to house. A 2009 court decision orders the prison population to be reduced to at least 137.5% capacity because overcrowding was deemed a violation of prisoners' rights as it negatively affected health and safety conditions of the prison.

Broader Sociological Impacts of Imprisonment

Imprisonment has sociological implications that reach beyond prison walls. While the construction and maintenance of prisons provides jobs and may improve the economic well-being of communities around prisons – which are often located in very poor and marginalized areas – imprisonment can hurt the economic and social stability of the communities prisoners are taken from and returned to. Before imprisonment, prisoners are members of communities and often serve as employees, parents, friends, etc. Incarceration may reduce crime by incapacitating criminals and deterring future crimes; however, removal of members from society greatly damages social bonds and increases stain and stigma. Loss of communal members, income, and political voice can result in diminished collective efficacy increased social disorganization, and increased crime rates. Even when prisoners are released back to their communities, the sociological effects of incarceration, such as stigma and disenfranchisement persist. As mentioned above, prisoners are disproportionately members of minority populations; therefore, the imprisonment cycle disproportionately impacts minority families and communities. Members of the dominant group in society, however, are more likely to be employed by prisons and therefore often benefit from the incarceration of others, hence reinforcing existing social disparities.

Incest, Inbreeding, and Their Consequences

Abstract

The global human population can be divided into societies in which legal marriage between close family members traditionally has been favored and practiced, and those in which it is avoided or precluded. Consanguineous unions are mainly chosen on social and economic grounds, whereas the reasons for their avoidance are based on religious teachings and the prevention of adverse health effects. Incest is the closest form of sexual relationship; currently it is a criminal offense in almost all the societies. Given the stringent legal prohibitions, information on the prevalence and adverse genetic effects of incest is scarce, and most of the available data are significantly biased.

Introduction

The terms 'inbreeding' and 'consanguinity' often are used interchangeably to describe sexual unions between couples known to share at least one common ancestor within a recent generation. In practice, they usually are applied to relationships between individuals who are genetically related as second cousins or closer. Other than in specific immigrant communities, 'consanguineous marriage,' a term derived from the Latin *con sanguineus* (of the same blood), is now rare in Western societies. However, marriage between close biological kin remains preferential in many parts of the world, including North and sub-Saharan Africa, the Middle East, and Central and South Asia. According to the cross-cultural ethnographic tabulations published by G.P. Murdock, 353 of the 763 societies examined either permitted or favored first and/or second cousin marriage (Murdock, 1987). Although the rates and types of consanguineous marriage typically vary according to religious norms, marital unions between first cousins are especially common, and in some countries (such as Pakistan) they can account for over 50% of all marital unions. By comparison, an incestuous relationship is a sexual union between biological relatives that is prohibited by law. Most commonly, incest is defined as mating between first-degree relatives (i.e., father–daughter, mother–son, or brother–sister) who predictably have 50% of their genes in common. However, in some countries the definition of incest has been widened to include half-sib and uncle–niece unions.

History of Human Consanguinity

It has been estimated that the number of breeding individuals in the out-of-Africa migration of early humans 60 000–70 000 years ago ranged from as few as 700 to a maximum of 10 000 adults (Bittles, 2012). These early groups followed a largely hunter–gatherer existence, and they quite rapidly dispersed through Asia and Europe and later, the Americas, in small kindred groupings. Therefore, their available mating choices must have been limited, which in turn led to the inevitability of at least some level of close-kin mating. Even after the establishment of settled communities and with early urbanization, by AD 1000 the global population is estimated to have totaled only 310 million persons; that is, less than 5% of the present world population. Geographical distance, poor communications, and the increasing influence of social stratification meant that marriage partner choices remained highly restricted with populations characterized by marital endogamy, that is, marriages confined within ethnic, geographical, religious, or social subcommunities (Bittles, 2012).

The early biblical texts contain many examples of reproductively successful consanguineous unions, including the marriage of Abraham with Sarah, his half-sister (Genesis 20:12), and Amram and Jochebed, the parents of Aaron and Moses, who were aunt and nephew (Exodus 6:20). At a later date the permitted degrees of marital relationships were extensively defined, with marriages up to and including uncle–niece permitted, but not aunt–nephew (Leviticus 18:7–18). Within Christianity, the Levitical guidelines were generally adopted by the post-Reformation Protestant churches, although in most denominations the closest form of approved martial union is between first cousins. By comparison, diocesan dispensation is required by the Roman Catholic Church for marriage between first cousins, and, with the exception of the Coptic Church, the Christian Orthodox faiths have a similarly proscriptive stance on consanguineous marriage. Attitudes toward close-kin marriage are generally favorable or at least neutral among the other major world religions, including Buddhism, Confucianism, the Dravidian branch of Hinduism, Islam, Judaism, and Parsi/Zoroastrianism. By comparison, in the Indo-European branch of Hinduism and in the Sikh religion, pedigrees may be examined for up to seven generations for males and five generations for females to ensure avoidance of a consanguineous union.

Attitudinal Changes toward Consanguineous Marriage in Western Societies

Prior to the mid-nineteenth century, first cousin marriages were quite commonly contracted in most Western societies, including countries such as Italy and Spain where a large majority of the population was Roman Catholic. From the 1850s, an often acrimonious debate ensued within the scientific and medical communities of North America and Western Europe on the biological effects of close-kin marriage.

In Europe, and in most countries that had been colonies of the major European powers, this debate resulted in few if any legislative changes. By comparison, within the United States the eventual outcome was the passage of laws at the state level to restrict or ban first cousin unions, even though the information on which these laws were promulgated was largely anecdotal rather than factual in nature. Restrictions on first cousin marriage were subsequently rescinded in the states of Michigan, New Jersey, and Ohio, but legislation on consanguinity was introduced in Maine in 1985 and Texas in 2005, with the net result that first cousin marriage is currently illegal or a criminal offense in 31 of the 50 states (Ottenheimer, 1996; Bittles, 2012) – despite a unanimous recommendation by the National Conference of Commissioners on Uniform State Laws in 1970 that all state laws on first cousin marriage should be repealed. Globally, the only other countries in which first cousin marriage is banned are the People's Republic of China and Taiwan, the Republic of Korea and the Democratic People's Republic of Korea, and the Philippines (Bittles, 2012).

Contemporary Societies in Which Consanguineous Marriage Is Preferential

As indicated in the preceding section, the current legal situation in the United States, China, the Koreas, and the Philippines differs markedly from the many other regions of the world where consanguineous unions are strongly preferential. The reasons for this preference are mainly social and economic in origin and include the strengthening of family relationships and the maintenance of family property and landholdings. Prenuptial arrangements are greatly simplified, female status and autonomy are enhanced, and the security of marrying a partner whose entire family background is known is perceived as a major benefit in ensuring both the initial success and the lasting stability of the union (Bittles, 2012). The existence of additional customary influences is, however, indicated by variations in the specific types of consanguineous marriage contracted. For example, while father's brother's daughter first cousin marriage is preferred in Arab Muslim communities, it is proscribed for Dravidian Hindus in South India and the Han Chinese, both of whom may instead contract marriage between a man and his mother's brother's daughter.

The Genetic Effects of Inbreeding

Because of the pejorative social connotations of the term 'inbreeding,' in human populations marriages between biological relatives usually are referred to as being consanguineous. In consanguineous unions the partners share genes inherited from one or more common ancestor, and, for example, in first cousin marriages, the spouses are predicted to have 12.5% of their genes in common. This means that on average their progeny will be homozygous at 6.25% of gene loci; that is, they will have inherited identical gene copies from each parent at these sites in their genome. Consequently, if the same mutant gene is inherited from both parents, the individual will express the associated disorder, either at birth or later in life depending on the nature and site of the mutation, thus contributing to the phenomenon of inbreeding depression that describes the adverse genetic effects of consanguinity.

The coefficient of inbreeding (F) is a numerical estimate of the degree of consanguinity of an individual, and so for first cousin offspring $F = 0.0625$, for example, as previously stated, on average they will have inherited identical gene copies from each parent at 6.25% of all gene loci. Similarly, the coefficient of inbreeding for the progeny of uncle–niece unions is $F = 0.125$, while for second cousin offspring $F = 0.0156$ (Bittles and Black, 2010; Bittles, 2012). In many communities there is a long, unbroken history of consanguineous unions, and the cumulative level of inbreeding may be significantly higher than the value calculated for a single generation. Under these circumstances, where a detailed, multigenerational pedigree is available, a correction can be applied to account for the effects of ancestral inbreeding using the formula:

$$F = \sum (1/2)^n (1 + F_A)$$

where F_A is the ancestor's inbreeding coefficient, n is the number of individuals in the path connecting the parents of the individual, and the summation (Σ) is taken over each path in the pedigree that goes through a common ancestor.

Incest

With a few notable exceptions the avoidance of sexual relationships between close family members is, and appears to have been, common to virtually all societies. Various explanations have been advanced for incest avoidance. One is Freudian guilt, based on the supposed attraction of a child for their parent of the opposite sex. Theories ascribed to Lévi-Strauss and others argue that incest serves both to maintain the existence of the family and to encourage the establishment of affinal relationships through marriage with other kin groups. According to the Westermarck hypothesis (Wolf and Durham, 2004), incest avoidance arises principally because of negative imprinting against close associates of early childhood. Studies conducted on individuals raised under mixed-sex, child-rearing regimes in Israeli *kibbutzim* have been cited in support of the negative imprinting theory, since these individuals rarely intermarried or entered into sexual relationships. Perhaps more convincingly, a detailed investigation of *sim-pua* marriage in Taiwan, whereby a girl is adopted with the expectation that she will marry the son of the adoptive family, demonstrated apparent aversion on the part of some intended spouses. Where a marriage did occur, *sim-pua* unions often were characterized by lower mean fertility and reduced marital stability (Wolf and Durham, 2004).

There have, however, been a number of societies in which dynastic incest was practiced over multiple generations, including the eighteenth and nineteenth Egyptian dynasties and the Ptolemaic and Roman periods in Egypt, Zoroastrian Persia, the Incas, and the royal families of Hawaii (Middleton, 1962; Shaw, 1992; Ager, 2005). In pharaonic Egypt, brother–sister or half-sibling unions were regarded as potent means of maintaining and strengthening the royal house and bloodline, although the pharaoh also had reproductive access to other females who were nonrelatives. Incestuous marriages additionally were contracted outside the ruling classes during the Roman period from the first to the third centuries AD, and in

the city of Arsinoe in Lower Egypt, brother–sister unions accounted for 19.6% of marriages with a further 3.9% between half-siblings (Scheidel, 1997). These marriages may have been atypical and in part stemmed from the restricted numbers of potential marriage partners in the minority Greek settler community. The underlying rationale for incestuous unions in Zoroastrian Persia appears to have been based on specific religious beliefs termed *xvétxvét* in Persian, and to have emerged just prior to the Islamic Arab invasion of AD 636. All three types of incestuous union – father–daughter, brother–sister, and mother–son – were advocated, and in each case they were described as being of especial religious merit, with their practice a means of expiating mortal sin.

Despite the claimed universality of the incest taboo, the prevalence of incestuous relationships in Western societies was estimated to be 5000 cases per million, but with much a higher prevalence reported in detailed studies conducted in the United States and Finland (Bittles, 2012). Most reports of incest have emanated from case studies conducted either on persons examined because of intellectual disability or in psychiatric clinics, which has led to the general conclusion that incestuous relationships are highly detrimental to those classified as victims. It has, however, been suggested that the outcome need not necessarily be psychologically damaging, with some women in stable relationships acknowledging prior father–daughter sexual relationships. Since incest is both illegal and widely regarded as morally reprehensible, it would be difficult to determine how common this latter response might be without exposing respondents to the risk of self-incrimination.

Biological Outcomes of Consanguinity and Incest

The initial major study into the biological effects of inbreeding was conducted by Dr Samuel Bemiss of Louisville, Kentucky, in 1858, based on reports forwarded by medical colleagues on the outcomes of unions ranging from incest to third cousin marriages. Literally thousands of additional studies have since been undertaken using a variety of sampling protocols, including pedigree analysis, household surveys, questionnaires administered to hospital in- and outpatients, Roman Catholic dispensation records, and surname analysis. In populations such as Dravidian South India, where uncle–niece ($F = 0.125$) and first cousin unions ($F = 0.0625$) are preferential and jointly account for some 30% of marriages, unions beyond second cousins ($F < 0.0156$) are of limited biological significance (Bittles et al., 1991). Conversely, in a country such as Finland where consanguineous unions are rare, or in endogamous communities in which close cousin marriage has been proscribed on religious grounds, more remote relationships including third cousin unions and beyond ($F \leq 0.0039$) can result in moderate levels of cumulative inbreeding through time and give rise to adverse clinical outcomes (Bittles, 2009).

Measuring the Biological Outcomes of Inbred Marriages

For several decades the detrimental health effects of consanguinity commonly were assessed in terms of lethal gene equivalents – genes that when homozygous contribute to early mortality. This method has largely been replaced by more direct methods of measurement, for example, comparing the rates of infant deaths among first cousin and non-consanguineous progeny in specific study settings (Bittles, 2012) and by genomic analysis to estimate the percentage of loci at which an individual is homozygous. Genome-wide analysis has been used to identify the presence of uninterrupted runs of homozygosity (ROH; extended segments of the genome at which all loci are homozygous), from which an individual's level of homozygosity can be directly calculated (McQuillan et al., 2008). With the introduction of whole genome and exome (i.e., the coding region of the genome) sequencing, estimates of the proportion of gene loci at which individuals have inherited identical gene copies from a common ancestor have become increasingly more accurate.

The Biological Outcomes of Incest

As first-degree relatives have on average 50% of their genes in common, the progeny of an incestuous union will be homozygous at 25% of gene loci, and so $F = 0.25$. Given the strongly antagonistic legal and social attitudes to incest, direct assessment of associated biological outcomes may be subject to significant ascertainment bias, since a detailed examination including determination of paternity may only be initiated if a child shows obvious symptoms of physical and/or intellectual disability. The net result is an overall paucity of data that may or may not reflect the incidence of incestuous pregnancies that successfully proceed to term. Problems also can arise in attempting to control for the potentially adverse effects of nongenetic variables, which include maternal and paternal age, parental disease, and unsuccessful attempted interruption of the pregnancy.

Direct Investigation of the Progeny of Incest

Table 1 comprises data from the five most comprehensive published studies of incest. The first and obvious observation is that very few cases have been systematically investigated, which is surprising, given the probable prevalence of incest and its prominence as a topic in the social and behavioral literature. Three of the studies were prospective, and in one investigation strenuous efforts were made to recruit matched nonincestuous controls (Adams and Neel, 1967). No control subjects were assessed in two of the other studies (Carter, 1967; Baird and McGillivray, 1982), and the brief report by Carter (1967) was further restricted by a lack of information on the physical and mental status of the parents or their socioeconomic background. In several studies the period of follow-up was brief, and so disorders with a later age of onset may not have been detected.

By far the largest survey was that of Seemanová (1971), which was conducted retrospectively on incestuous births reported in Czechoslovakia between 1933 and 1970. An ingenious approach to the problem of controls was employed, with the outcomes of incestuous matings compared to those of pregnancies undertaken by a subset of the same women and unrelated partners. Unfortunately, the methodology could not overcome the fact that the physical and mental status of these women, who formed 33% of the original total, was

Table 1 Health status of the progeny of incestuous relationships ($F = 0.25$)

Country of origin	*Sample size*	*Follow-up (years)*	*Deaths/severe defects*	*Other defects/mild intellectual disability*	*Normal*	*Authors*
United States	18	0.5	6	5	7	Adams and Neel (1967)
United Kingdom	13	4–6	4	4	5	Carter (1967)
Czechoslovakia	161	1–37	65	18	78	Seemanová (1971)
United Kingdom	23	4–25	11	5	7	Bundey (1979)
Canada	21	0.5–19	9	4	8	Baird and McGillivray (1982)
Total	236		95 (40.3%)	36 (15.3%)	105 (44.5%)	

significantly superior to the remainder of the study group. In addition, many of the incestuous pregnancies occurred when the women had just completed menarche; that is, became physiologically capable of reproduction, with mean and modal ages of 18.9 and 16 years in the father–daughter matings and 19.9 and 14 years in the brother–sister matings, versus 24.9 and 21 years in the married pregnancy group (Bittles, 2012). As very young maternal age is significantly associated with an adverse pregnancy outcome, failure to control for the age discrepancies between the test group and their half-sibs significantly detracts from the validity of the study findings. With such small numbers significant bias can be introduced by a single individual; for example, the Seemanová study in which an alcoholic male had fathered five children with three daughters. All five children were born with some form of abnormality, and three died within 10 days of birth.

How then should these five data sets be assessed? Clearly, the mean total rate of death and physical or mental disability of ~55% is very high. But, as previously indicated, the collection of data on this subject is extremely difficult, and, as acknowledged by several authors, control for important nongenetic variables may have been seriously incomplete. In the two studies for which unrelated reference groups were available, 9 of the 113 control children died or had a serious defect (8.0%). Thus the mean excess level of death and severe defect in the offspring of incestuous unions was 32.3%, not all of which was necessarily genetic in origin.

Comparison of Incest with Other Categories of Consanguineous Union

A second method of estimating the probable levels of defect in the progeny of incestuous matings is based on information gained from legal consanguineous unions. For example, it is assumed that as the progeny of an incestuous mating will have a coefficient of inbreeding of $F = 0.25$, their levels of inherited disease leading to disability or death will be four times larger than in first cousin offspring ($F = 0.0625$). The main advantage of this approach is that information on first cousin unions is plentiful, and as a legal form of martial union it is less likely to be subject to bias during data collection. A potential disadvantage is that the relationship between the level of consanguinity and the occurrence of deaths and defects may be nonlinear, with disproportionately larger increases in the prevalence of deaths and defects at closer degrees of inbreeding. This situation could arise if incest was associated with increased rates of conditional lethals; that is, genes that are only expressed under especially stressful circumstances, as might be encountered in an incestuous pregnancy. To date, there has been no evidence that conditional lethals are expressed in the progeny of close-kin unions. Therefore, the excess mortality rate of 3.7% derived for deaths among first cousin progeny (Bittles, 2012) can be applied to estimate the prevalence of lethal defects in an incestuous pregnancy; that is, ~15% excess deaths. Likewise, based on first cousin survey data, the mean excess morbidity among incestuous offspring would predictably be ~13–16% (Bittles, 2012), suggesting a total excess death and major disability in children born to first-degree relatives of approximately 30%.

Conclusions

The data currently available on the outcomes of both legal consanguineous marriages and incestuous relationships merit further examination and updating. Since the major studies undertaken by Schull and Neel and their colleagues in Japan from the late 1940s to the 1970s, initially in Hiroshima and Nagasaki (Schull and Neel, 1965), and later on the island of Hirado, no comparably detailed investigations have been attempted, despite the remarkable epidemiological transition that has occurred during the last two generations. Across Asia, genetic disorders are becoming increasingly obvious as deaths due to infectious diseases decline in number and proportion, and early childhood mortality is replaced by extended morbidity. This change is especially important among couples in consanguineous unions, where higher rates of rare genetic disorders are to be expected involving both autosomal recessive and polygenic disorders. In fact, because of better access to diagnostic and health care facilities, the burden of genetic disease will probably be most obvious and of greatest significance among migrants from Asia and Africa now resident in North America, Western Europe, and Australasia, who have chosen to continue their tradition of close-kin marriage. With respect to incest, it is curious that the voluminous social and behavioral literature is still so inadequately matched by comparable reports on biological outcomes. Studies to identify the precise nature, extent, and timing of any genetic defects that may be expressed are needed, since in a proportion of cases the children of incestuous unions may be offered for adoption. The advent of whole genome analysis and exome sequencing will greatly facilitate this process and provide information of previously unparalleled insight and sophistication (Rehder et al., 2013). In the interim, appropriate caution should be exercised in judging and reporting the biological outcomes of all categories of close-kin union.

Abstract

Why do people avoid sexual relations with close relatives? And why do they punish and condemn as inhuman the few exceptions? The many theorists who have addressed these questions fall naturally into one of two mutually hostile camps – constitutionalists and conventionalists. The former include, most notably, the Finnish scholar Edward Westermarck who argued that the proximate cause of incest avoidance is early association and the ultimate cause, the dangers of inbreeding. The latter include E.B. Tylor, Leslie White, Claude Levi-Strauss, and a motley collection of Marxists. They attribute incest avoidance to the incest taboos and argue that the taboos were instituted to secure various social advantages. They follow Freud in assuming that human beings are naturally inclined to mate and marry in the family. After more than a 100 years of intense debate most scholars now agree that Westermarck was right in attributing incest avoidance to the dangers of inbreeding, but there is still no generally accepted explanation of the incest taboos. The conventionalist view has been eroded by a flow of evidence indicating that the taboos are not necessary to achieve whatever social advantages exogamy may entail, but constitutionalists have failed to provide a convincing alternative. All they have to offer is the suggestion that the taboos are by-products of incest avoidance.

What is commonly called the incest problem consists of two separable parts: incest avoidance and the incest taboos. Thus the problem raises two questions about human behavior: Why is it that, for the most part, humans avoid sexual relations with their close relatives? and Why is it that they disapprove of and often punish people who do not avoid sexual relations with their close relatives? The second question is complicated by the fact that the scope of the incest taboo varies from society to society. In most societies the taboo is extended beyond the family, but the direction of the extensions varies widely. Where many societies prohibit marriage with paternal relatives but allow, and in some cases prefer, marriage with maternal relatives, just the opposite is the case in many others.

Most attempts to answer these questions belong to one or the other of two radically different traditions, what are best called the 'constitutionalist tradition' and the 'conventionalist tradition.' Constitutionalists typically emphasize the dangers of inbreeding; conventionalists, the social advantages of a rule that requires marriage outside of the family. The best known of the constitutionalist arguments was the work of the Finnish philosopher *cum* anthropologist Edward Westermarck. Following the train of thought put in motion by Charles Darwin, he argued that the dangers of inbreeding made human beings naturally averse to sexual relations with anyone with whom they were reared. Humans typically avoided sexual relations with their close relatives because these were the people with whom or by whom they were reared.

The most notable conventionalist contribution is the independent, but almost simultaneous work of the American materialist, Leslie White, and the famous French structuralist, Claude Levi-Strauss. Arguing that inbreeding is only dangerous for inferior stock, they rejected Westermarck's suggestion that early association inhibits sexual attraction, insisting instead that Freud was right in claiming that (1953[1920]: pp. 120–121). Both authors then argued that the incest taboos were instituted to force people to marry outside of the group in which they were reared, their purpose being to create larger, more effective social units by binding together families that might otherwise remain isolated self-perpetuating units. Because this required suppressing a natural inclination, Levi-Strauss once said of the incest taboos, "It is there, and only there, that we find a passage from nature to culture, from animal to human life." (1960: p. 278).

The controversy aroused by these two approaches to the incest problem highlights the importance of three questions: Does inbreeding have deleterious consequences? Is incest common? and Does early association inhibit sexual attraction? The answer to the first question was not finally agreed on until researchers took advantage of the fact that cousin marriage is common in many parts of the world and calculated the excess mortality and major disability rates of the offspring (Bittles, 2005). Using this evidence, they estimated that for the offspring of brother/sister, father/daughter, and mother/son unions, the combined rates would be somewhere between 22 and 36%, more than sufficient to generate a strong evolutionary bias favoring any behavior that reduced the frequency of incest (Wolf, 1995). Evidence from all the societies for which we have evidence says that incest is rare among sexually mature adults. The female is almost always a child and the male a stepfather or a father who was rarely at home when his daughter was a child, or if he was, did not help care for her. Initiated when the female is a child, relationships of this kind are typically terminated by her at puberty, the result being that most of what is counted as incest is the abuse of children.

Evidence relevant to the third question has been slow coming because children reared together are usually siblings, making it difficult to determine if they avoid one another because of early association or because of a barrier imposed by the incest taboo (Wolf, 2014) that has finally displaced Freud in favor of Westermarck comes from two unlikely sources, the early Israeli kibbutzim where communal child rearing was the norm, and South China where it was once customary for families to give away most of their female children shortly after birth and rear in their places wives for their sons. Though they were reared together as intimately as brothers and sisters, kibbutz children were not constrained by an incest taboo. To

the contrary, they were encouraged to marry by elders anxious to keep them in the collective. The fact is, however, that as long as their association began before age three or four, they never married among themselves and, according to reliable observers, never engaged one another in premarital sex. In China, by contrast, the children who were reared together as future mates were forced to marry, the result being abnormally low fertility and abnormally high divorce and adultery rates. Thus, taken together, the Israeli and Chinese cases argue that children who are reared together will not marry if they are not forced to do so, and, if they are forced, will behave as one would expect if early association inhibited sexual attraction.

As the answers to these three questions emerged in the 1960s and 1970s, scholarly opinion shifted from a marked preference for the conventionalist approach to the incest problem to a general if often reluctant acceptance of the constitutionalist approach. The view that the incest taboos are necessary to suppress a natural preference of the kind posited by Freud could not withstand the combined impact of evidence showing that incest is biologically deleterious, rare among sexually mature adults, and generally inhibited by early association. What most constitutionalists have failed to recognize, however, is that while this evidence grounds their explanation of incest avoidance, it does not explain the incest taboos. All contemporary constitutionalists like E.O. Wilson have to say about the taboos is that they "seem to have arisen from the Westermarck effect" (1978: p. 37) or are "by products" of the "deeper, more urgent causes behind incest avoidance" (1998: p. 180).

A great deal more is needed for a complete solution to the incest problem, most importantly an explanation of why people condemn behavior that does themselves no harm and why the range of people vulnerable to such condemnation varies from society to society.

Income Distribution and Inequality: Measurement Issues

Abstract

Recent research establishes strong evidence that economic inequality in the US has increased over the past few decades, but that the amount of increase varies by the measure used. In this article, we will examine the components of measures of inequality – the 'who, what, where, when, why, and how' of inequality measures. We show that what resource measure, which data source, and whose standard of living all affect the measurement of both the level of trend in inequality. We also provide examples of how these choices affect the increase in inequality in the US.

The significance of the distribution of resources and its importance to overall economic well-being was recognized by Adam Smith in his characterization of the invisible hand. Smith (1761) stated: "The rich only select from the heap what is most precious and agreeable. They consume little more than the poor, and in spite of their natural selfishness and rapacity … They are led by an invisible hand to make nearly the same distribution of the necessaries of life, which would have been made, had the earth been divided into equal portions among all its inhabitants, and thus without intending it, without knowing it, advance the interest of the society, and afford means to the multiplication of the species." David Ricardo (1821) continued along this theme in discussing how the "… produce of the earth …" is "… divided among the three classes of community …" and concludes "To determine the laws which regulate this distribution, is the principal problem in Political Economy …."

The increased attention to inequality in the twentieth century was stimulated by Simon Kuznets who emphasized the importance of the distribution of income in his seminal paper (Kuznets, 1955). He concludes: "Without better knowledge of the trends in secular income structure and of the factors that determine them, our understanding of the whole process of economic growth is limited; and any insight we may derive from observing changes in countrywide aggregates over time will be defective if these changes are not translated into movements of shares of the various income groups."

After a period in the 1960 and 1970s, where one economist remarked that "studying inequality was like watching the grass grow" (Aaron, 1978), subsequent and continual increases in inequality have brought it to a point where it is being brought 'back in from the cold' and has re-entered mainstream economic thought (Atkinson, 1997). This interest continues today, with an increase in the evaluation and estimation of inequality. The *2012 Economic Report of the President* stated: "The confluence of rising inequality and low economic mobility over the past three decades poses a real threat to the United States as a land of opportunity." Isabel Sawhill (2012) stated that "2011 was the year of inequality" and Paul Krugman (1992) introduced the "staircase vs picket fence" analogy, where he concluded that the change in income gains between 1973 and 1993 followed a staircase pattern with income growth rates increasing with higher income quintiles.

From the beginning, Pareto (1897) demonstrated the importance of individual record empirical data in evaluating the distribution of income. Watkins (1908) and Persons (1909) also used household data to estimate levels of income inequality. Since then, the study of income inequality has progressed, with new measures, new data, examining the impact of taxes, benefits, and so on. Corrado Gini (1921), Hugh Dalton (1920), Jan Pen (1971), Max Lorenz (1905), Henry Theil (1967), and Anthony B. Atkinson (1970) have each created particular and complimentary measures of inequality. The Gini coefficient has become one of the most used measures of inequality as it summarizes the Lorenz curve in an easily understood one-digit index. Not only does the Census Bureau (and CBO) release an annual measure of the Gini for income, this measure is also used in international work (see OECD, Luxembourg Income Study, World Bank, and others).

Some indices are more sensitive to changes at the top (Theil, 1967) or bottom (Atkinson, 1970) of the distribution, but the Gini is the most used measure in the empirical literature.

Other, more recent measures include the share of income received by the top 1 or 5% (see Piketty and Saez, 2003), the decile ratio (90th to 10th percentile values), the ratio of the value at the 90th percentile to the middle (median or 50th percentile) value, and the ratio of the 50th percentile to the 10th (Voitchovsky, 2005; Brandolini and Smeeding, 2009). While all of these measures demonstrate the recent increase in inequality, they all show different levels and rates of increase, with some focusing on changes in the bottom or the top of the distribution as opposed to a single number like the Gini. In this article, we will examine the components of measures of inequality – the 'who, what, where, when, why, and how' of inequality measures, and the ways in which these choices impact the measurement of inequality.

The Who, What, Where, When, Why, and How of Inequality

To determine the economic measurement of inequality, we need to decide whose standard of living we are measuring and

how we are going to measure it and update it over time. The various summary statistics described earlier are only good in so far as one begins with the basics of the measure itself. Far too often in measurement of economic inequality, the beauty of the summary measure far exceeds the accuracy of the concept one is measuring. The following questions must be answered:

- What: Which resource measure is going to be used?
- Who: Whose standard of living is being measured?
- When: What time period is used?
- Where: Do the measures differ by geographic location?
- Why: What is the purpose of these measures?
- How: Which summary statistics and data are going to be used?

What: The Choice of Resource Measure

The most inclusive concept of income and consumption derives from the suggestions of Haig and Simons. Haig (1921) stated that income was "the money value of the net accretion to one's economic power between two points of time" and Simons (1938) defined personal income as "the algebraic sum of (1) the market value of rights exercised in consumption and (2) the change in the value of the store of property rights between the beginning and end of the period in question."

Economists have used the equation that income (Y) equals consumption (C) plus the change in net worth (ΔW) as the working definition of Haig–Simons income ($Y = C + \Delta W$). No household survey, however, has the necessary variables to create a full measure of Haig–Simons income. In an attempt to relate all three components, the Canberra Group Handbook on Household Income Statistics (2011) states: "Household income receipts are available for current consumption and do not reduce the net worth of the household through a reduction of its cash, the disposal of its other financial or non-financial assets, or an increase in its liabilities."

Most studies of income and its distribution include money income, but do not examine changes in assets, and only a few examine the impact of capital gains (e.g., CBO, 2011, 2012; Piketty and Saez, 2003; Smeeding and Thompson, 2011; Wolff et al., 2012). The 'more complete income' (MCI) concept in Smeeding and Thompson (2011) is based on Haig–Simons income and estimated using Survey of Consumer Finance data. They define MCI as earnings and net transfers and include that portion of capital income received as capital gains and royalties. They subtract reported interest, rent, and dividends and include an imputed return to all forms of net worth in order to capture the concept of the change in net worth. Using MCI, Smeeding and Thompson (2011) find a larger concentration of income at the top of the distribution.

There is agreement that inequality increased during the past three decades using various measures of income, but the magnitude of the increase depends on the income measure used and the unit of observation. For example, the Census Bureau estimates that the inequality, using the Gini coefficient, of pre-tax cash income for households (adjusted for family size) increased 19% between 1979 and 2010. CBO (2012) estimates an increase of 21.6% for market income inequality (between 1979 and 2009), and Saez (2012) shows that the share of taxable income obtained by the top 1% doubled between 1979 and 2009. See also Kenworthy and Smeeding (2014) for a summary and comparison of these measures.

Many economists have suggested that consumption may be a more appropriate indicator of permanent income (see Danziger and Taussig, 1979; Cutler and Katz, 1991; Slesnick, 1991, 1994). Johnson and Shipp (1997) were among the first to show different trends in income and consumption inequality. Slesnick (1991) and Cutler and Katz (1991) demonstrated that consumption inequality was lower than income inequality, and that the increase in both income and consumption inequality was similar during the 1980s. Later, Krueger and Perri (2006) identify the divergent trends in income and consumption inequality during the 1990s. Most recent research shows that consumption inequality is less than income inequality, and its increase is less than the increase in income inequality (see Krueger and Perri, 2006; Heathcote et al., 2010; Meyer and Sullivan, 2013; Fisher et al., 2013).

Then wealth or net worth itself may be used as the measure of inequality. Here the evidence is more sketchy and dependent on valuing both private and public pensions as well as businesses and financial holdings. For recent studies of wealth inequality, see Wolff (2012) and Pfeffer et al. (2013).

Who: Whose Standard of Living?

To examine the distribution of income, researchers need to determine whose income to evaluate or the unit of analysis. Many measures of the standard of living use household (or family) resources, while others use individual earnings or income. Households with more members may need additional income to be equally well-off as smaller households. Most studies use family or household income and adjust it by an 'equivalence scale' to obtain equivalent family resources. Some studies using income tax data are limited to tax units, which suggest a much smaller unit for income sharing (Piketty and Saez, 2003). A measure of well-being for individuals is obtained by using the family size (multiplied by the household's sample weight) as a weight. This method assumes that all members of the household have and share the same level of resources (Johnson, 2004). Earlier research has shown that the choice of equivalence scale can have dramatic effects on both the level of and trend in the standard of living (Coulter et al., 1992; Johnson et al., 1998). This literature has focused on the effect that equivalence scales have on both inequality and poverty measures.

One of the most common scales is the single-parameter constant-elasticity equivalence scale reviewed by Buhmann et al. (1988) and Ruggles (1990), which is used most often in international comparisons of inequality (see Atkinson et al., 1995). In general, the constant elasticity scales are given by (family size)^e, in which e is the scale elasticity. Notice that if the elasticity equals one, then the scale equals family size, there are no assumed economies of scale in living arrangements, and the equivalent resources are simply the per-capita resources. Alternatively, if the elasticity equals zero then there is no adjustment for family size, there are complete economies of scale in living and the marginal cost

of another person is zero. Following the suggestions by Ruggles (1990) and Buhmann et al. (1988), much research uses an elasticity of 0.5. This scale indicates that the resources for a two-person family must be 41% more than that of a single-person family for the two-person family to have the same standard of living as the single-person family.

Some scales adjust for more than just the number of adults and children in the family. For instance, the scales implicit in the poverty thresholds adjust for the age of the household head, and the new three-parameter scale (see Betson, 1996; Short et al., 1999) used in the Census's Supplemental Poverty measure provides more economies of scale between singles and childless couples, which are more similar to those in the poverty scale. Slesnick (1994) presents scales that depend on family size, the age, race, and gender of the household head, and regional location and the farm/nonfarm status of the household.

The choice of equivalence scale can impact the level and trend of inequality. Coulter et al. (1992) demonstrate that the constant elasticity equivalence scale yields a U-shaped relationship between inequality and the scale parameter, *e*. Johnson (2004) compares alternative scales and shows that the choice of scale has a dramatic effect on the relative standard of living of different families. A lower equivalence scale implies that the family's resources will be adjusted upward, hence, increasing their equivalent resources. For example, single adults will have a higher standard of living relative to the reference group under the three-parameter scales (compared to the poverty scales). In addition, the Slesnick scales produce a higher standard of living for single parents than any of the other alternatives. Jenkins (1994) and Johnson (2004) also show that different constant elasticity scales yield different changes in inequality over time.

When: Choosing a Time Period and Adjusting the Standard of Living over Time

Any measure of the standard of living must be based on particular reference period and be adjusted by the changes in the cost-of-living that occur during the time period. In discussing poverty measures, Foster (1998: p. 337) claims that "the key distinction between absolute and relative thresholds is not seen in the specific values at a given date, but in how the values change as the distribution changes." Most studies use annual measures of income. However, consumption measures that are more similar to permanent income (or average income over a period of years) yield less inequality. Alternatively, monthly or quarterly income yields higher inequality. Hence, the period of time matters. The Canberra Report (2011) suggests using annual income, which has become the norm, even if it is likely too long a period for low-income families and too short for measures of permanent income, especially for higher-income households (Gottschalk and Smeeding, 1997).

When measuring 'real' living standards, not just income shares, cost of living adjustments are frequently constructed using a price index such as the CPI. The literature on the CPI suggests that it may be over adjusting the cost of living, that is, the real changes in the standard of living may be larger than those found using the CPI (see Boskin et al., 1996; Meyer and Sullivan, 2011). Other research shows that absolute poverty rates and changes in median resources are also affected by the price index used (see Slesnick, 2001; Meyer and Sullivan, 2011).

While different price indexes (or cost of living adjustments) lead to a variety of changes in the *level* of the median and changes in the levels of various quintiles, they do not affect the *trend* in inequality. Slesnick (2001), however, shows that using household-specific price indexes can have a small effect on the trend in inequality. Johnson (2004) and Fixler and Johnson (2013) show the impacts of price indexes on the changes in the median income. However, inequality will be impacted only by using price indexes that vary with income. Recent suggestions in Broda and Weinstein (2008) and Gordon and Dew-Becker (2008) suggest that price changes may be lower for lower-income groups, which would lead to a smaller increase in inequality, but there is a question as to whether they properly measure changes in prices for services which are consumed by the poor.

Where: How Are the Measures Adjusted for Differences in Geography?

Similar to the adjustment for family size, it could be that some areas in the country (or even different countries) could have different costs. Slesnick (2001) uses equivalence scales that depend on the region and the urbanity of the geographic area. The Bureau of Economic Analysis (BEA) has constructed a regional price parity index to adjust personal income and show that the range across counties narrows, and hence, inequality across the country is less than using the unadjusted income. Moretti (2013) and Deaton (2010) discuss other implications of using geographically adjusted income in comparing wages across the US and income internationally. Especially in making international comparisons, the recent Canberra Report (2011) suggests using price index adjustments, and highlights an example from Canada, which uses interarea price indexes.

How: Which Summary Statistic and Data Source?

As we have suggested, much research focuses on the levels and trends in the Gini coefficient to evaluate inequality, but Atkinson (1970), Sen (1997), and Theil (1967) evaluate a variety of inequality measures and their properties. As shown in the Census Current Population Report (DeNavas-Walt et al., 2013), the changes over the past 30 years have been similar for all four measures. Others focus on the ratio of particular percentiles (e.g., 90th/10th percentile ratio, or 90th/50th). Often, techniques are used to estimate differences for the changes at the alternative ends of the distribution, such as a Pareto distribution for the upper tail of income which is often under-reported in surveys. In some comparisons across countries or survey years, arbitrary high and low values are imposed on survey data. For example, incomes may be bounded from below at zero (or at a very small number) thereby omitting negative incomes (as in self-owned businesses which suffer a loss) or bounded above at some multiple of median or mean incomes to protect confidentiality in the top of the distribution (Atkinson et al., 1995).

The final choice is that of data set. The Census Bureau (see DeNavas-Walt et al., 2013) and CBO use the Current Population Survey (CPS) to create a comprehensive income measure, and several other top income data sources can be used to estimate inequality trends. These include income tax records from the IRS (analyzed by Piketty and Saez, 2003; Saez, 2012; Atkinson et al., 2011) and the Federal Reserve Board's Survey of Consumer Finances (SCF). Analysis using these data sources suggests that income inequality has risen dramatically at the very top of the distribution. The analysis by Saez (2012) of IRS data through 2010 finds that the share of federal pre-tax Adjusted Gross Income held by the richest 1% of households more than doubled between 1979 and 2007. The CBO 'comprehensive income' measure (not adjusted for taxes) shows that the top 1% share of total income rose from 9.3 to 19.4% over the 1979–2007 period. Smeeding and Thompson (2011) use the SCF data to calculate a 'more comprehensive income' (MCI) measure which combines standard income flows with imputed income to assets. They show that the top 1% share of MCI rose from 18% in 1989 to 22% in 2007. Armour et al. (2013) compute implicit capital gains and losses each year from 1989 to 2007 and show that inequality declines and the top share falls using their techniques.

Impacts of Choices

Figure 1 compares the changes in the income received by quintiles using six measures of income. This figure illustrates how many of the measurement choices discussed earlier impact the level and distribution of income, including the choice of resource measure, equivalence scale, inequality measure, and price index. The level of inequality is often measured using the Gini index or a variant of the Lorenz curve using the share of income for each quintile. This figure shows the increase in mean income for each quintile and demonstrates an increase in inequality since higher quintiles experienced larger increases in income during this time period (portraying a staircase pattern). Many others have shown similar results (DeNavas-Walt et al., 2013; CBO, 2012; Kenworthy and Smeeding, 2014; Burkhauser et al., 2010).

The six measures in Figure 1 include the Census money income and equivalized income measure (DeNavas-Walt et al., 2013), two measures of the CBO after-tax income with alternative methods for valuing health care benefits (see CBO, 2012), and two measures from Burkhauser et al. (2010). The extent of the increase in inequality differs across the six measures of income, with the largest increase occurring for the CBO after-tax income measure with the fungible value of Medicare and Medicaid.

Looking at the changes for the middle quintile illustrates the variety of results regarding the economic well-being of the nation. Burkhauser et al. (2010) and Meyer and Sullivan (2011) suggest that the median income has increased more than what others suggest, mainly referring to the changes presented by the US Census Bureau (DeNavas-Walt et al., 2013). Evaluating the changes for the middle quintile highlights the impacts of using equivalence scales. Due to the fall in average household size during this period, the increase in equivalized income is larger here than for household income. In addition, because of the

Figure 1 Percentage growth in mean quintile income using alternative definitions of income (adjusted for inflation using CPI-U-RS), 1979–2007. Congressional Budget Office, 2012. The Distribution of Household Income and Federal Taxes, 2008 and 2009. CBO, report; Burkhauser, R., Larrimore, J., Simon, K., 2010. A "Second Opinion" on the Economic Health of the American Middle Class. NBER Working Paper 17164, National Bureau of Economic Research; DeNavas-Walt, C., Proctor, B.D., Smith, J.C., 2013. Income, Poverty, and Health Insurance Coverage in the United States: 2012. US Census Bureau, Current Population Reports, P60–245, US Government Printing Office, Washington, DC.

increases in Medicare and Medicaid as well as in employer subsidized insurance, including these in income at their cost yields a larger increase in income at the median. Finally, using a price index that shows less inflation than the CPI-U-RS (such as the PCE deflator used in CBO, 2012) would yield a larger increase in the median income.

This figure also shows changes in inequality. All measures display a staircase pattern, with each higher quintile showing a larger increase in income, regardless of concept or measure. However, there are differences. For example, the equivalized income shows a larger increase in inequality during this period (see also DeNavas-Walt et al., 2013; Kenworthy and Smeeding, 2014). Since Medicaid and Medicare benefits are received by households with lower income, and since employer health insurance subsidies are constant across all covered workers in a company, these subsidies are a larger fraction of compensation for lower wage employees. It follows that there are larger increases in resources at the lower quintiles and hence, a smaller increase in inequality when one includes the actual cost of health insurance in such estimates. The method used to account for Medicare and Medicaid benefits affect the change in inequality. Recently, the CBO switched to using the cash value (or actual cost) of benefits instead of the fungible value, which places a lower value of benefits for lower-income households.

Finally, the data source matters, especially with respect to the treatment of very high income households. As can be seen in the changes for the top decile, the CBO measures show much larger increases. This is because the other four measures use the CPS household survey while the CBO adjusts the household survey with tax records to account for the under-representativeness of high-income households.

To convert this information into an inequality measure and show the changes in inequality over time, one would use the share of income for each quintile. The changes in these shares would show much more dramatic differences by quintile, with the top quintile increasing its share of income between 1979 and 2007. One can use these shares to compare the Gini coefficients over time. **Figure 2** shows five alternative Gini coefficients. Two of them use similar data shown in **Figure 1** – the CPS and the CBO measures. The CBO measure is the before-tax measure more comparable to the Census money income. While the changes between 1979 and 2009 are similar for these two measures, between 1979 and 2007 the CBO measure increases more than the CPS measure because of the treatment of high-income households.

The other three are from two different data sources. The MCI measure is from Smeeding and Thompson (2011) and represents a comprehensive after-tax measure that includes financial gains, while the disposable income and consumption measures are from Fisher et al. (2013). As shown in **Figure 2**, the trends in the after-tax measures are similar, and over the entire 30-year period the trends in all income measures are similar. As expected, the Gini for consumption is lower than that for income, but increases at about 75% the rate of income inequality.

Why: The Purpose of the Measure

Each of the choices – who, what, where, when, and how – have different implications for the levels and trends of inequality. As

Figure 2 The Gini coefficient using various income measures and a consumption measure. DeNavas-Walt, C., Proctor, B.D., Smith, J.C., 2013. Income, Poverty, and Health Insurance Coverage in the United States: 2012. US Census Bureau, Current Population Reports, US Government Printing Office, Washington, DC, pp. 60–245; Smeeding, T.M., Thompson, J.P., May 2011. Recent trends in the distribution of income: labor, wealth and more complete measures of well-being. Research in Labor Economics, 1–49; Congressional Budget Office, 2011. Trends in the Distribution of Household Income between 1979 and 2007. CBO, report; Congressional Budget Office, 2012. The Distribution of Household Income and Federal Taxes, 2008 and 2009. CBO, report; Fisher, J., Johnson, D., Smeeding, T., 2013. Measuring the trends in inequality of individuals and families: income and consumption. American Economic Review 103(3), 184–188.

a result, researchers need to decide on the purpose of their evaluation when making these choices, whether it is the overall changes in inequality, the redistributive impacts of government taxes and transfers, or the differences between annual and permanent income. Each of these questions may require different data and inequality measures. One should never mix and match measures, as this will provide a misleading picture of the levels and trends in inequality. For example, Leonhardt (2012) combined Census, CBO, and the Saez measures of income to evaluate changes in particular percentiles in one diagram.

Many researchers attempt to make cross-national comparisons of inequality (see OECD, 2011; Brandolini and Smeeding, 2009). As mentioned earlier, the Canberra report recommends a common definition of income along with similar choices in equivalence scales and price indexes in order to make international comparisons. The LIS (see http://www.lisdatacenter.org/) Income Measure is similar in spirit to the Canberra recommended measure. However, many of the alternative choices presented earlier are not all available for international comparisons and researchers need to be aware of these differences.

One common thread is to try to understand the forces which drive inequality: trade, skill-biased technical change; the growth of the capital share of national income relative to the labor share; 'winner take all' markets; and so on. Simple generalizations on causes are not easily found in this literature. Another purpose is to evaluate the effects of inequality on things we care about, such as health, voting, lifespan, happiness, economic growth, equality of opportunity, and intergenerational mobility. Kenworthy and Smeeding (2014) provide a very brief summary of this growing literature.

Conclusion

In this brief survey, we have attempted to convey some of the issues involved in measuring economic inequality and its trends. Longer treatments can be found in the *Oxford Handbook of Economic Inequality* (Salverda et al., 2009) and the *Elsevier Handbook of Income Distribution* (Atkinson and Bourguignon, 2000). Suffice it to say that with inequality rising in most rich nations (for example, see OECD, 2011) and despite the widespread coverage of the top 1% of income earners, we still have much to learn about inequality, its source, and its origins. It is indeed time to bring inequality back into the fold of mainstream economics as Atkinson (1997) has suggested.

Income Inequality

Dennis Gilbert, Hamilton College, Clinton, NY, USA

Abstract

This article first defines income and describes the sources of income data, the issues surrounding the measurement of household income, and the most common measures of income inequality. It then examines household income trends in affluent countries since the 1970s and shows that the distribution of household income has become more unequal in most, but especially in the US and UK. It includes that Skill Biased Technological Change, globalization, and the waning influence of wage-setting institutions, along with shifts in household composition and behavior, are driving the rising inequality of household incomes in affluent countries.

Income may be defined as the amount of money and other resources received by an individual or household over a specified period of time (e.g., $2000 per month, $500 000 in 2015). It is distinguished from wealth, which is the value of assets held at a point in time (e.g., $250 000 on 30 June 2015). In recent years, there has been increasing political and social science interest in the distribution of income, stimulated by evidence of growing inequality among households in affluent countries, the central focus of this article. Concern with the distribution of income is, for many, rooted in questions of social justice: should societies permit a few to live opulently, while others struggle to attain the basics of food, clothing, shelter, health care, and education? Does the skewed distribution of income fairly reflect differences in the contributions individuals make to the common welfare? But interest in income distribution is also encouraged by more practical concerns with the possible effects of rising income inequality on economic growth, democratic governance, social mobility, physical and mental health, family stability, and rates of violent crime (Wilkinson and Pickett, 2009; Hacker and Pierson, 2010).

Sources of Income

Households receive income from one or more of the following sources: (1) earnings from jobs held by one or more members of the household; (2) self-employment income from small businesses and professional practices; (3) capital income in the form of interest, dividends, rents, royalties, or capital gains derived from financial assets and real property owned by the household; (4) public transfers such as social security benefits, farm subsidies, and assistance to low-income households; (5) private transfers including pension payments, alimony, and gifts. Job earnings are the major income source for most nonelderly households, but the weight of job earnings and other income sources varies across the distribution. If all the households in a typical developed country were lined up in a parade, from lowest to highest income, it would be found that those at the beginning of the parade are the most dependent on public transfers and hold one job or none; that households in the middle and toward the end of the parade are likely to have two employed members; and that households at the very end of the parade receive a significant, if not the predominant share of their income from self-employment and capitalist sources.

Income Data and Measurement

A household, the basic unit of analysis in most income studies, may consist of a family, unrelated persons residing together, or an individual living alone. The two basic sources of income data are household surveys, such as the US Current Population Survey or the French Household Budget Survey, and administrative records, especially those based on income tax returns. Annual government surveys are the most comprehensive income data source. They are typically based on large samples of the national population and collect essential demographic and economic information from households. A subset of surveys, such as the Panel Study of Income Dynamics in the US and the European Community Household Panel, track smaller samples of households over a period of years to understand long-term variation in income.

Surveys tend to underestimate income at the upper end of the distribution, presenting a problem for studies of income inequality. Tax records, based on legally defined tax reporting units, provide better coverage of high incomes, but are otherwise less comprehensive, since not everyone pays income taxes and those who do are not asked to provide detailed information about themselves. Synthetic estimates of the income distribution, such as those developed by the US Congressional Budget Office, integrate data from both sources (www.cbo.gov/publication/44604).

The LIS Cross-National Data Center (formerly, the Luxembourg Income Study) collects national income data sets from upper and middle-income countries and makes it available to researchers in a compatible, microdata format. LIS is the source of much of the data employed in comparative studies of income distribution. The LIS website (www.lisdatacenter.org) also provides comparative summary income statistics ('Key Figures'), which will be used in this article.

Measuring income for research purposes presents a series of conceptual and practical issues, including the appropriate time frame, unit of analysis, and elements to be included in the definition of income. The guiding assumption in these matters is that income is intended as a measure of living standard or

relative welfare. Annual household income is the key variable in most studies. The use of annual income is problematic because incomes are known to vary more from year to year than household consumption does. Income averaged over several years (available in some cases from panel studies) might be a superior indicator, but the data that most researchers depend on are collected in official annual surveys. Household income, pooled from multiple sources, is regarded the best available indicator of the welfare of household members, even if it cannot be assumed that income is shared equally among them. Some studies, including those based on LIS data, adjust incomes for household size, assuming that, at a given income level, the members of larger households will have a lower standard of living; adjustment factors allow for economies of scale – families big and small, for example, only need one kitchen.

Analysts may distinguish between market income and disposable income. In broad terms, the former is the sum of income from job earnings, self-employment, and capital sources, while the latter – believed to be a better welfare measure – is market income plus public transfers, less direct taxes. Disposable income may incorporate other items, including the value of noncash transfers, such as food stamps or subsidized housing, and the imputed value of rent for owner-occupied housing.

Measuring Inequality

There are several common ways of measuring income inequality. One approach looks at the proportional distribution of income shares across segments of the population. For example, in the United States in 2012, the bottom quintile of households received about 3% of all household income, while the richest quintile absorbed 51%; only the fourth quintile, at 23%, received close to a proportionate share (U.S. Census, 2013: 40). A telling measure of concentration at the top is the share of income flowing to the richest 1% of households. Another inequality measure, percentile ratios, permit comparisons for specific ranges of the distribution. For example, the ratio between incomes at the 90th and 50th percentiles in United Kingdom rose from 1.764 to 2.126 between 1974 and 2010, indicating growing inequality in the upper half of the distribution (LIS Key Figures).

The Gini index is the most frequently used of several summary measures of inequality derived from the Lorenz curve, which plots cumulative income shares against cumulative percentage of the population. A hypothetical Lorenz curve following an upward slanting 45° diagonal would indicate perfect equality (the bottom 10% receives 10% of all income, the bottom 50% receives 50%, etc.) The Gini coefficient is a measure of the degree of deviation from the diagonal, indicating the extent of income inequality. It ranges from 0 (perfect equality) to 1 (perfect inequality). The Gini coefficients for Denmark, the United States, and Mexico in 2004, were, respectively, 0.228, 0.372, and 0.457 (LIS Key Figures).

Trends in Income Inequality

Three broad generalizations can be made about the changing distribution of income in affluent countries. First, income inequality, by diverse measures, has increased in most high-income countries since the 1970s. The extent, timing, and exact pattern of rising inequality vary among countries, but the general direction of change is unmistakable. Second, this growing inequality has typically been marked by income polarization, with fewer households in the middle-income range (commonly defined as incomes between 75 and 125% of the median income) and more at the higher or lower levels (Some have characterized this phenomenon as the disappearance of the middle class, a notion that conflates middle class with middle income. In fact, many workers with what would be considered middle-class occupations enjoy incomes well beyond the median). Third, the rising inequality of recent decades is a reversal of the declining inequality of the post-World War II era – a shift often described as the great U-turn. Here the evidence is thinner but suggestive, since comparable income data for the earlier period is often lacking.

Table 1 records income inequality levels and trends for 15 affluent countries for which comparable LIS statistics were available. Countries are ranked in descending order by Gini coefficient for the last year of the period indicated. These numbers are based on disposable income, adjusted for household size. Corresponding market income coefficients would, of course, be higher, since they would not reflect the equaling effects of progressive taxation and government provided social benefits including retirement support. For example, the market income Gini coefficient for 24 mostly high-income OECD countries in the mid-2000s was 0.450, compared to a disposable income coefficient of 0.300 (OECD, 2008: 53107).

The right hand column in the table shows the percentage change in each country's Gini index from a point in the late-1970s or 1980s to the mid-2000s. Among the nations listed, the English-speaking countries, especially the US and UK, have high levels of inequality and the Scandinavian countries have relatively low levels. All except 4 of 15 countries have experienced rising inequality over the last two to three decades. In most of these countries, the proportion of the population in the middle-income range, as defined above, shrank between

Table 1 Inequality of disposable income in affluent nations

	Gini	*Percentage Change*
United States 1979–2007	0.378	26
United Kingdom 1979–2007	0.357	34
Ireland 1987–2007	0.328	−9
Spain 1980–2007	0.318	−4
Australia 1987–2003	0.312	11
France 1978–2005	0.312	−10
Italy 1986–2008	0.306	1
Canada 1975–2007	0.289	1
Luxembourg 1985–2007	0.276	16
Austria 1987–2004	0.269	19
Finland 1987–2007	0.264	28
Germany 1978–2007	0.263	1
Norway 1979–2004	0.256	14
Denmark 1987–2004	0.255	−11
Netherlands 1983–2007	0.252	1
Sweden 1981–2005	0.197	20

Figure 1 Growth of family income and GDP per capita, 1950–2000. Reproduced from Gilbert, D. 2015. The American Class Structure in an Age of Growing Inequality. Sage, Los Angeles, p. 95.

1985 and 2004 (Atkinson and Bandolini, 2013: 85; Alderson and Doran, 2013).

The Anglophone countries, with their high and growing income inequality, were especially notable for the rising share of income claimed by the top 1% since 1970. The extreme case was the United States, where the income share of the richest percentile climbed from under 10% in the mid-1970s to over 20% by the beginning of the new century. In contrast, the share of the top percentile was relatively flat in continental Europe and Japan over that same period (Piketty and Saez, 2013).

Figure 1 describes the great U-turn phenomenon for the United States with the shifting pattern of income growth before and after 1975. It shows that the prosperity of the postwar period was broadly shared among families, with the bottom quintile experiencing the fastest growth and the top 5% the slowest. The pattern of the second period, beginning in 1975, is an exaggerated mirror image of the first. The growth of family incomes became steeply stratified, with the top 5% enjoying a distinct advantage. Remarkably, the growth of GDP per capita during both of these 25-year periods was about the same, close to 75%, but the benefits of growth were distributed very differently. Sweden, Finland, West Germany, and, to a more modest degree, Canada also experienced a U-turn, traced by the path of the Gini coefficient, with declining inequality through the early 1970s into the early 1980s and rising inequality thereafter; France, an outlier, saw declining income disparities from the early 1970s to the end of the twentieth century (Brandolini and Smeeding, 2009: 88–89; Alderson and Nielsen, 2002).

Growing Inequality: Labor Market Factors

Increasing wage inequality among men has been the primary driver of the growing inequality in household incomes. From 1980 into the twenty-first century wage dispersion increased for both men and women, but especially for men, in most developed countries. It appears that technological change and globalization have narrowed prospects for lower-skilled workers in these countries, while opening new opportunities for those with sophisticated skills. In manufacturing, digitally controlled robotic technology, outsourcing of labor-intensive intermediate goods, and cheap imports from low-wage countries have sharply reduced demand for semiskilled production workers and constrained their wages. Computerization of routine office tasks and the 'offshoring' of some through the Internet have had a similar, if less dramatic effect on demand for clerical workers. Many unskilled workers were channeled into the low wage, routine, service sector jobs that could not be offshored. In contrast, at the high end of the labor market, those with valued technical, analytic, and managerial skills – from corporate executives to software engineers and financial analysts – have been the winners in a changing economy. The most commonly cited indicator of these trends is the growing wage gap between high school educated workers and those with college and graduate degrees, especially notable in the US and the UK. Another indicator is the widening skill disparity in unemployment rates, especially among the young in some continental European countries (Katz and Autor, 1999; Blau and Kahn, 2009; Liu and Grusky, 2013).

Economists commonly describe this transformation of the labor market in terms of 'Skill Biased Technological Change' (SBTC) and give special emphasis to the spread of digital technologies as the catalyst for SBTC. Although globalization and SBTC can be regarded as complementary forces, both 'biased' against the unskilled, there is no consensus among economists about the relative importance of globalization in growing wage dispersion. Research has focused on the effects of international trade. But globalization may be influencing the labor market in less obvious ways, from the offshoring of services to the threat, often explicit, that aggressive wage demands will drive production abroad (Katz and Autor, 1999; Lemieux, 2008; Wood, 1994; Alderson and Nielsen, 2002; Freeman, 2009).

The growing inequality in earnings also reflects the declining influence of wage-setting institutions, such as labor unions, minimum wage laws, centralized bargaining, and wage indexation mechanisms, such as Italy's *scala mobile* (abandoned in 1992). Where they are strong these institutions shield workers from market forces and tend to compress earnings at the lower end of the distribution. But their strength is highly dependent on state support, which has been waning in many countries. In the United States, for example, the real value of the minimum wage, periodically reset by legislation, sank 12% from 1967 to 2011; private sector union membership declined from about 35% in the mid-1950s to under 7% in 2012 (Mishel et al., 2012: 279–280; Gilbert, 2015: 217). Between 1980 and 2000, the coverage of the labor force by collective bargaining agreements declined in six of twelve affluent countries, remained unchanged in three, and modestly expanded in three others. The loss of coverage was greatest in the UK, the US, and New Zealand, countries that also experienced substantial increases in wage inequality. In contrast, France, where coverage was high and became slightly higher, wage disparities shrank (Blau and Kahn, 2009: 189; Visser and Checchi, 2009). While all developed economies were subject to the global and technological forces described above, these differences in labor market institutions help explain the considerable variation among countries in outcomes (Lemieux, 2008; Katz and Autor, 1999).

Growing Inequality: The Top 1%

Various explanations have been offered for the steeply rising share of income flowing to the top 1% in the United States and other Anglophone countries since the 1970s. Capital sources have traditionally accounted for most income at this level, and probably continued to do so for the very wealthy, the top 0.1%. The expansion of financial markets and the increased international mobility of capital, the growth of international trade, and the emergence of profitable new sectors associated with information technology all contributed to a healthy rise in capital income. But by 2000 the majority of the income of the top 1% came in the form of job earnings (Leigh, 2009: 161; Piketty and Saez, 2013). In part, this phenomenon reflected the broader growth in rewards to individuals with highly valued skills. Some observers have noted a tendency, especially in the United States, to confer outsized rewards on top performers – so-called 'superstars' – in fields as diverse as finance and medicine (Rosen, 1983; Frank and Cook, 1995). The most salient example is the compensation of the CEOs of major American corporations, often climbing into the tens of millions of dollars. Rising scale and changing social norms have been suggested as explanations for the spread of superstar rewards beyond their accustomed arenas of entertainment and sports. CEO compensation has clearly increased with the scale of global business. But the CEOs of European and Japanese corporations, operating on a similar scale, are not so richly rewarded as their American peers, and it is hard to see how scale has contributed to the emergence of superstar physicians or superstar university presidents. It may well be that, in some countries, social norms regarding appropriate or just compensation levels have shifted since the 1970s – at least among those with power over pay decisions.

Cross-national differences in tax regimes, reflecting broader political differences, have also influenced the fortunes of the wealthy in developed countries. For the Anglophone nations, reductions in top marginal tax rates since 1970 contributed an estimated one third to one half of the rise in the income shares claimed by the top 1% – first by increasing the amount of market income retained after taxes and, in the longer term, by boosting the accumulation of income producing capital (Leigh, 2009: 165; Hacker and Pierson, 2010).

Growing Inequality: Household Factors

Explanations of rising income inequality in affluent nations, usually focus on market income. But market income is channeled through households, whose composition and behavior affect the ultimate distribution. Three household level factors deserve attention: the increasing proportion of female-headed families; the growing labor force participation and earnings of wives; and 'assortive mating,' the rising tendency for husbands and wives to have similar levels of education and income-earning potential (Espying-Andersen, 2007; McCall and Percheski, 2010; Burtless, 2009; Blank, 2011; Harkness, 2013).

Evidence is best for the first of these factors. In affluent countries generally, female-headed families – especially single-mother families – have become increasingly common. By the first decade of the twenty-first century, the proportion of children in single-mother families was over 20% in the US and the UK and generally high in northern Europe, though notably lower in Spain, Italy, and Greece (LIS Key Figures). Single-mother families typically have lower than average incomes because they are likely to be single-earner families, because women's wages tend to be lower than men's, and because lone mothers must balance competing work and family obligations on their own. Cross-national research indicates that the increasing proportion of female-headed families has measurably contributed to increasing income inequality in affluent countries since the 1970s, except in Scandinavia, where easy access to child care supports the labor participation of single mothers (Espying-Andersen and Myles, 2009: 646–647).

The growing contribution of wives to household earnings is also a factor in rising inequality. A widening gap separates the rising numbers of husband-wife, dual earner households from those with single-earners, especially if they are single parents. But even among married-couple families, wives' increasing contribution may be enlarging income disparities because women's wages, like men's, are growing more unequal, because better educated women are more likely to work than their less educated sisters, and because assortive mating at the top increasingly links high-income earners. The effect of wives' earnings is greatest in southern Europe, where women's labor force participation rates remain low, except among highly educated women with strong earning potential. Its effect is less significant in the US, UK, and Scandinavia.

Conclusion

A combination of labor market and household factors has been reshaping income distribution in high-income countries since the 1970s. Their effect has, in varying degrees, been intensified or attenuated by political/policy influences, evident in the strength of wage-setting institutions, marginal tax rates, and access to state-funded child care. While there is broad agreement among researchers about the growth of income inequality in most developed countries, there is less consensus regarding the causes of this trend and their relative importance.

Income Taxes

Abstract

Following a discussion of the nature of income taxation, the article reviews theory and evidence of the effects of the income tax on individual behavior with respect to labor supply, saving, portfolio choice, and tax evasion. It also discusses the role of the tax in income redistribution and the design of an optimal tax system that combines the concerns for economic efficiency and distributive justice. It also reviews a number of recent proposals for tax reform in different countries.

In the eyes of the taxpayer, the income tax is the most visible form of taxation and therefore also politically the most controversial. Controversies surround the issues of how the income tax affects individual behavior in areas such as labor supply, saving, home production, and tax evasion. Even more controversial, obviously, is the use of the income tax to redistribute income, which raises the more normative question of how progressive the income tax ought to be.

The Nature of Income Taxation

The income tax is the prime example of a direct tax; it is levied directly on the incomes of the individual consumers in the economy, and it can be designed to take account of the individual circumstances of the taxpayer. In contrast, indirect taxes are levied on anonymous market transactions and are paid at the same rate irrespective of the taxpayer's income, number of children, age, health – to mention just a few of the taxpayer characteristics that have over time been taken into account in the design of the personal income tax. It is this tailoring of the tax to the individual's ability to pay, which makes it a potentially important instrument for the redistribution of income and for reducing differences in the standard of living among individuals and families.

The definition of taxable income varies in the legal systems of different countries and over time. Labor income – wages and salaries – forms the central element of the tax base. To this is added income from capital in the form of interest, dividends, etc. However, income from capital is a more elusive concept than income from labor. Thus, countries differ in the extent to which capital gains are subject to taxation, and they differ in the extent to which noncash income, such as the imputed income from owner-occupied housing, is subject to tax. Perhaps even more importantly, rules differ regarding the deductibility of negative capital income, such as interest payment on mortgage loans. Tax laws also differ in the extent to which they allow the deduction of particular expenses, such as the cost of travel to work, the cost of child care, trade union fees, etc.

These differences in the tax base may reflect different perceptions among policy makers of what is a just and fair tax system; they may also reflect differences in the balance of political power among various special interests. What is clear is that different legal definitions of the tax base create different economic incentives for the taxpayers as well as different consequences for the after-tax distribution of income.

The income tax may be progressive, proportional, or regressive. A proportional tax is one where the average tax rate is constant; the proportion of income paid in tax is the same for all levels of income. Note that this implies that the marginal tax rate – the percentage tax paid out of a small increase in income – is also constant. In a progressive tax system the average tax rate increases with income, and this implies that the marginal rate is higher than the average rate. Finally, in a regressive tax system the average tax rate is decreasing, with the marginal tax rate being lower than the average rate.

Countries differ considerably both in their legal definitions of the tax base and in the degree of progressivity of their income tax schedules. There is also significant variation between countries as regards the importance of taxes on income as a source of revenue. To illustrate, in 2010 according to official Organisation for Economic Co-operation and Development statistics, the share of income taxes (as levied on all sources of income and inclusive of social security taxes) in total tax revenue varied from about 45% in Chile, Mexico, and Israel to around 70% in countries like Norway, Switzerland, and the United States. Of course, these percentage shares are reflected in a correspondingly high share of revenue from indirect taxes in the former group of countries and a low share in the latter.

The Income Tax and Economic Behavior: Labor Supply

How do variations in the income tax rate affect the labor supply of individuals and households? The economic theory of labor supply takes its point of departure from a model of a single individual who faces certain market opportunities. In the simplest version of this model, the wage rate per hour worked is constant, so that earnings are proportional to hours worked. In deciding how many hours to work, the individual takes account both of the fact that higher earnings make it possible to consume more, but that it also costs something in the form of less leisure. At the optimal number of hours worked, it must be the case that the subjective marginal value of leisure equals the real after-tax wage rate. For longer hours of work the subjective value of leisure is higher than the wage rate; at shorter hours it is less.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71043-9

Now consider what happens if the marginal tax rate increases. Two effects can be identified. First, since the reward to labor at the margin falls, there is an incentive to work less; this is called the substitution effect. Second, since the tax increase means that the taxpayer is less well off than before, his marginal valuation of leisure falls; this is what is known as the income effect, which in itself tends to increase work effort. Clearly, the two effects pull in opposite direction, so that it is not possible to formulate any clear-cut hypothesis about the connection between the marginal tax rate and labor supply.

A common objection to this theory is that there are in fact few individuals who are able to choose their hours of work freely, and that the theory, therefore, tends to focus attention on a problem of little importance. In the short run this is certainly true for a large number of employees. However, the theory can be interpreted in a number of different ways to make it applicable to many more aspects of labor supply. Consider, for example, a young worker who is entering the labor force and considering different job opportunities. Some jobs are offering long hours and high earnings, while others promise more leisure time at the cost of lower earnings. The occupational choice between job alternatives can in fact be modeled in a way that is formally similar to the hours of work model, and the substitution and income effects of taxation emerge in this setting as well. The same is true of models of the choice of retirement age; a tax increase decreases the reward to a further extension of one's working life and creates an incentive to earlier retirement (the substitution effect), but it also makes it necessary to work longer than before to achieve a given standard of living during retirement (the income effect).

The consideration of retirement raises the more general issue of labor force participation. For some people, taxation may influence their decision on whether or not to participate in the labor market. Income from labor, provided that they decide to work, will be compared to the income that they can count on if they do not work. Alternative sources of income may be income from capital, earnings by family members, income derived from black market work or other illegal activities as well as social assistance and other forms of public support. The tax rate that is relevant for the participation decision is not so much the marginal as the average rate. The crucial point is how much income from labor will be reduced by the total amount of tax paid on this income.

A number of attempts have been made to estimate models of labor supply and taxation using econometric methods. Since the nature of the data sets employed in these studies differs considerably, one might expect that the results would be highly specific with respect to the country, the time, and the nature of the industry to which the data pertain. This is true to some extent, but there are also some general results that characterize a large number of studies. One is that the labor supply of women tends to be more elastic with respect to tax changes than that of men. When women's marginal tax rates go up, they tend to work significantly less, whereas for men one typically finds very small effects. Attempts have also been made to follow the theoretical model and estimate the substitution and income effects separately. One then frequently finds that the reason the total effect for men is small is not that both effects are insignificant, but rather while each is of substantial magnitude, they tend to cancel each other. Moreover, women's participation rate tends to be more sensitive to taxation than that of men.

How is one to interpret the result that the labor supply of women is more elastic than that of men? The most natural explanation is that in most data sets, women tend to be the secondary breadwinners in the family; they tend to work shorter hours and have lower earnings than their male partners. Variations in family labor supply in response to tax changes will, therefore, most naturally take the form of adjustments in the hours of work and labor force participation by women.

In the theoretical framework sketched above, leisure was implicitly defined as the amount of time not spent working in the labor market. But as a matter of fact people spend a lot of time in household work; studies of time use tend to show that household work takes up about as much time on the average as work in the labor market. The substitution effect of higher taxes in favor of leisure is accordingly also in favor of household work; in other words, the income tax 'subsidizes' labor used in household production.

The tax rates that are relevant for the theoretical and empirical study of labor supply are most naturally considered to be simply the statutory rates of the tax law. However, in some contexts it is necessary to take a broader view. Suppose that an individual or household receives a transfer, in cash or in kind, which is income contingent; in order to qualify for it, one's income must not exceed a certain limit. Imagine now that the income of a particular household increases from somewhere below this limit to somewhere above. This increase is subject to the statutory rate of tax, which in the case of a low-income household, can be supposed to be relatively low. But in addition the household loses its transfer, and this loss is in economic terms exactly like a tax increase. The combined effect of the statutory rate and the loss of the transfer payment results in an effective tax rate, which could be much higher and might even exceed 100%, thus creating a powerful disincentive to work among low-income families, often referred to as a 'poverty trap.' This is not just a theoretical possibility but has been identified as an empirical fact in the tax and transfer systems in a number of countries. Clearly, it is very important to consider the interaction between tax and transfer systems in order to avoid unintended and unfortunate consequences of their combined effects.

The Income Tax and Economic Behavior: Saving and Portfolio Choice

The base on which the income tax is levied includes income from capital as well as from labor. A simple extension of the theoretical framework so far is to imagine that the individual lives in two periods, and that he saves some of his labor income in the first period. This will then become available – with interest added – in the second period. Interest income is subject to tax. What happens to saving when the tax rate increases?

As in the labor supply case, we can identify a substitution and an income effect of an increase in the marginal tax rate. When the tax rate goes up, the after-tax interest rate falls and there is an incentive to save less; this is the substitution effect. On the other hand, the lower the net-of-tax interest is, the more it is necessary to save in order to achieve a given level of future

consumption, and this is the income effect. The substitution and income effects clearly work in opposite directions. But we also need to take account of the fact that some people are not net savers in the first part of their life. Instead they borrow with the loan to be repaid with interest in the later part of their life cycle. If the interest on the loan is tax deductible, a higher rate of tax provides an incentive to borrow more, i.e., to save less. This, again, is the substitution effect. But now the lower interest rate makes it possible to borrow more than before without having to reduce future consumption; thus the income effect on saving for a borrower is negative, not positive. Since some people are borrowers and some lenders, the income effect for all consumers together might not be very significant and the substitution effect would tend to dominate. Empirical studies also tend to show that there is in fact a negative tax effect on saving, although the magnitude is not always very strong.

This picture of tax effects on saving seems to assume that all saving takes the effect of lending or borrowing in some kind of homogeneous asset. In reality, of course, people hold a portfolio of assets (housing, bank deposits, mortgage debt, shares, etc.,), and the income tax can therefore be expected to influence not only the aggregate amount of saving but also the composition of the savings portfolio. This is particularly so since the income tax law in many countries does not provide for the taxation of different asset returns at a uniform rate. While interest on bank deposits is often taxed at the statutory rate, interest on some types of bonds may be tax exempt, capital gains may be tax free provided one has held the stock for a sufficiently long time, and the returns from collector's assets like art, antique furniture, rare books, and stamps are usually not taxed at all. Empirical studies also seem to indicate that portfolio composition is indeed very sensitive to tax effects.

In the academic literature there is one type of tax effect on portfolio choice which has received special attention by economic theorists. Some assets are relatively safe in the sense that their return can be predicted with a high degree of certainty; others are more risky. Could the income tax be expected to change the balance between safe and risky assets in savers' portfolios? Suppose that there is full loss offset, so that any negative returns on risky assets can be deducted against other income. Then one can deduce, basically from the assumption that the individual saver is averse to risk, that an increase in the rate of income tax will induce him to invest more in the risky asset than before. The explanation is that although the government takes a share of his expected return, it also shares in the risk, thereby protecting him from the full consequences of low or negative returns. This theoretical insight has had a considerable influence on the way that economists view the bias of investment incentives related to the income tax, but the hypothesis is not an easy one to test on empirical data. The major reason for this is, as argued above, that there are so many other tax incentive effects on portfolio composition that the risk substitution effect becomes very hard to trace.

The Corporate Income Tax

All income ultimately accrues to private individuals, so that the tax on corporate income or profits is in the last instance also a tax on individual consumers. In fact, some economists have suggested that it might be a good idea to abolish the tax on corporations and instead collect all income from corporations at the hands of the individual stockholders. But abolishing the tax on corporations might not be a politically popular issue, and in addition there are some real economic arguments why it should be preserved. One is that collecting the tax at the corporate level helps to reduce incentives for tax avoidance and evasion; another is that it is an efficient way to collect some tax revenue from foreign owners of domestic companies who are not subject to the domestic tax on personal income.

In the theoretical literature there is a further argument in favor of the corporate income tax. Assume that corporations maximize profits and that markets are efficient. Then it would be desirable to have taxes that do not lead to any distortions of production and investment decisions in corporations. But if corporations are subject to a (say) 40% tax on profits, the decisions that would maximize profits in the absence of tax are obviously the same as would maximize 40% of profits. Hence the corporate income tax is neutral; it collects revenue for the government without leading to any distortions of decisions at the firm level and leaves the efficient market outcome unaffected.

However, this picture is very much simplified. The main reason for this is that the tax definition of corporate income is in several respects different from the theoretical concept of profits. One important source of deviation between the two lies in the treatment of real capital depreciation. The real depreciation of a piece of machinery or a building or another type of capital equipment during a year is part of the costs of the corporation, and in order for the corporate income tax to be neutral, real capital depreciation should count as part of the costs in arriving at a definition of taxable income that corresponds to true profits. But a corporation may employ thousands of different types of real capital, and it is not possible for the tax authorities to allow for the deductibility of true depreciation for all of these. Instead they typically allow standard depreciation rates for large groups of capital assets such as machines, buildings, transportation equipment, and so on. But this means that for some types of capital the corporation is allowed to deduct less than the true depreciation, for others more. In its interaction with the tax depreciation rules the corporate income tax in fact works as a selective tax on some types of capital equipment and as a subsidy on others. Similar issues may arise regarding interest deductibility, stock valuation, and capital gains both on real and financial assets. It is, therefore, not surprising that empirical studies, e.g., Jorgenson and Yun (1991), tend to show that there are substantial tax effects on production and investment decisions in corporations.

Income Tax Evasion

Tax evasion is an illegal activity, which aims to hide taxable income from the view of the tax authorities. It should be distinguished from tax avoidance, which consists in trying to reduce one's taxable income by exploiting the tax law while staying inside its boundaries. While the distinction between the two may sometimes be unclear, there are at least a large

number of cases that definitely belong in the evasion category; these are sometimes referred to as the hidden or black economy.

Tax evasion is a risky activity. By holding back information from the tax authorities, there is always a risk of being discovered, in which case one typically faces a penalty rate on the unreported income. The gain on a dollar of unreported income, i.e., the regular rate of income tax, must be balanced against the probable loss, which is the probability of detection times the penalty rate of tax. When the regular income tax rate goes up the gain increases, and this tends to encourage evasion e.g., in the form of work in the hidden economy. Theory seems to support the common concern that the high-tax level encourages cheating and dishonesty. However, this should not lead us to expect that high-tax countries necessarily have more tax evasion than countries with lower tax levels. The extent of evasion depends not only on the level of income taxation, but also on a number of additional social and economic factors, such as the level of tax enforcement and efficiency of tax collection as well as the general attitude among taxpayers toward government and the public sector. All of these factors are likely to vary considerably among countries.

Theoretical hypotheses in this area are particularly hard to confront with empirical data; in the nature of things, there are no official statistics for the hidden economy, and survey research faces some special difficulties in making individuals answer questions truthfully. A number of the empirical studies that have been made uses very indirect methods, like deducing the size of the hidden economy from the public's holding of cash, and the reliability of this kind of approach is highly disputed; see e.g., Cowell (1990). More standard approaches tend to yield estimates which indicate that the hidden economy has a volume of 2–10% of the gross national product of the official economy. Many studies also indicate that evasion is higher for self-employed than for salaried employees. This is in good accordance with the theory, for wages and salaries are usually reported directly by employers, so the probability of evasion being detected is much higher for employees than for the self-employed, implying that evasion is a less risky gamble for the latter.

It should be added that the emphasis on rational risk-taking behavior as an explanation of tax evasion does not imply that in the economist's view of the world all taxpayers are completely amoral, reporting their income truthfully only when a cost–benefit calculation has shown them that evasion does not pay. There are strong indications that many taxpayers report their true income even when underreporting could easily go undetected, and at least part of the explanation for this are likely to be found in peoples' moral aversion to lying about their true income. However, it remains a fact that a large number of people do engage in tax evasion activities, and these are likely to consider the risk-taking aspects of their activities in a manner which is rational, given their preferences and attitudes to risk. For further discussion see e.g., Sandmo (2012).

The Income Tax and the Redistribution of Income

It is widely accepted in most countries that the income tax should take account of the taxpayer's ability to pay, and the most common interpretation of this principle is that the tax should be progressive. This raises the question of whether the income tax in fact has led to a situation where posttax or disposable income is more evenly distributed than pretax or factor income. In most empirical studies the answer to this question is an affirmative one, although the estimated magnitude of the redistributive effect varies substantially. A general feature of empirical studies is that the redistributive effect is smaller than the formal progressivity of the income tax schedule would lead one to expect, and the main reason for this is the role played by exemptions or tax credits. As an example, suppose that mortgage interest payments are fully deductible and that their share of gross income tends to increase with income. Then, as gross income increases, taxable income increases less than disposable income in percentage terms, and this mitigates the increase in the effective average tax rate. The importance of this effect has been well documented in a number of studies, such as Wagstaff et al. (1999).

From a theoretical point of view one would expect that the progressivity of the tax system would have an effect on pretax incomes. The markets for at least some occupations would react to high marginal tax rates by increasing gross incomes; this is the problem of tax incidence. Since the gross incomes that would have existed had there been no income tax or a purely proportional tax, are unobservable, this observation makes it much more difficult to study the redistributive impact of the income tax. In this connection it is interesting to observe that countries with a high degree of pretax inequality also tend to be the ones with high posttax inequality, and moreover that the redistributive impact of the income tax is high in some countries, which have a low degree of inequality in pretax incomes (Wagstaff et al., 1999). However, it is not clear whether this means that the incidence problem is in fact of little importance or whether there is some other explanation. If public opinion is dominated by egalitarian social and political values, these may be reflected not only the progressivity of the tax system, but also in the structure of pretax earnings.

The Income Tax, Economic Efficiency, and the Equality–Efficiency Trade-Off

The income tax has always been under attacks from critics for leading to distortions of economic incentives and consequently to inefficient social outcomes. The criticism has been especially focused on the distortion of work incentives, which leads to incentives to work less than would be desirable from a social point of view. As pointed out in Section The Income Tax and Economic Behavior: Labor Supply above, there is clear evidence for such an effect in the case of women, while for men the net effect tends to be very small. However, in considering the efficiency loss from income taxation, it is the substitution effects, and not the total effects, that should concern us. The reason is that the income effects would always be present, whatever the form of the tax system (and given the amount of revenue to be collected). The substitution effects are the direct consequences of the distortion of wages as efficient market prices, and if our sole concern is with efficiency, we should attempt to design the tax system in such a way as to make the substitution effects as small as possible. Similar concerns are relevant in judging the

effects of income taxation on saving and investment behavior. The taxation of interest income might lead consumers to save less and to invest in the assets or industries with the most favorable tax rules rather than in those with the highest rates of return.

However, efficiency is not the only standard by which to judge the income tax. As demonstrated in the progressive structure of the income tax in most countries, one of the goals of income taxation is to redistribute income from the rich to the poor, and the gains on the side of redistribution must be set against the cost of a less efficient allocation of resources. This is a recurrent problem in the design of economic policy; there is a need to choose a trade-off between equality and efficiency. However, if more equality is a real goal of economic policy, it should presumably be worth some cost in terms of less economic efficiency in order to achieve it. These ideas have been formalized in the theory of optimal income taxation as first formulated by Mirrlees (1971). This theory attempts to show how the optimal schedule of income taxation – in particular, the taxation of income from labor – depends both on the efficiency cost, as measured by the elasticity of labor supply, and by the social attitude to inequality. On the one hand, the more elastic labor supply is with respect to the marginal tax rate, the lower should the tax rates be. On the other hand, the more pronounced society's taste for equality is, the stronger is the case for a progressive tax schedule. Clearly, what economic theory can contribute to this issue is not to produce exact numbers, but to help establish a logically consistent way of thinking about a complex issue that involves both economics and ethics (Sandmo, 1999). By varying the assumptions made about value judgments, the structure of labor supply and the distribution of earnings, the theoretical analysis helps to clarify how conclusions about the desirable form of income taxation can be derived from a consistent framework of economic analysis.

Proposals for Tax Reform

A number of proposals have been advanced for basic reform of the income tax system, frequently motivated by the desire to improve the terms of the equality–efficiency trade-off. For example, is it possible to achieve the same degree of redistribution at a lower efficiency cost? Tax reforms in a number of Western countries during the last couple of decades have tried to move in this direction by decreasing the formal degree of progressivity in the tax system, while at the same time eliminating many of the deductions and exemptions that had contributed to a lower degree of effective progressivity. Studies of the American (Auerbach and Slemrod, 1997) and Scandinavian (Agell et al., 1996; Sørensen, 1998) reforms of the 1980s and 1990s, do in fact conclude that their overall effects have been to leave the redistributive effects of the tax system virtually unaffected, while removing many of the tax distortions both in labor and capital markets. The Scandinavian countries were pioneers in introducing the principle of dual income taxation whereby labor income is taxed at progressive rates while income from capital is taxed at a flat rate (the same for personal and corporate income), which is considerably lower than the marginal tax on labor income. The main motivation behind this version of the income tax has been to reduce the opportunities for tax arbitrage with respect to capital income, thereby leading to a system, which is arguably both more efficient and more equitable.

A more radical proposal for reform is the adoption of a so-called flat tax. There are several versions of this, but one that was proposed by Hall and Rabushka (1995) and has been much discussed in the United States involves imposing a constant marginal tax rate on all income above a certain exemption level. Although the name of the tax indicates that the major point in its favor is the simplification of the tax structure, probably its more important features are the elimination of a large number of deductions and a more uniform taxation of income from capital. In this, it is in line with the general trends in the reforms of the 1980s and 1990s.

Another reform, whose intellectual history goes back a long time and which was much discussed during the late 1970s and early 1980s was the possible adoption of an expenditure tax (Meade Committee, 1978; Kay and King, 1990). Although the expenditure tax is often seen as an alternative to the income tax, it may also be regarded as simply a particular form of income taxation. Briefly, an expenditure tax is an income tax with full deduction for all saving, but with negative saving being added to income. What is taxed is accordingly expenditure or consumption, not income. There are two main claims for the expenditure tax. First, since differences in the standard of living between persons are primarily related to their consumption, not income, consumption is the more logical base on which to level a progressive tax. Second, the treatment of saving and dissaving leads to a more uniform and, therefore, more efficient taxation of capital income. Although neither the expenditure tax nor the flat tax have so far achieved any direct political success, the political and economic debates over these proposals may indirectly have had considerable influence on the reforms that were actually adopted in the following years.

A recent ambitious attempt at the analysis of tax reform is the Mirrlees Review in the United Kingdom. Its final report (Mirrlees Review, 2011) proposes a series of reforms of the UK tax system, including a more transparent and coherent schedule of progressive income taxation with rates that reflect the available evidence on behavioral responses to taxation. The report is based on a collection of research articles by an international group of leading experts on the economics of taxation, including several that have a direct bearing on the design of the income tax (Mirrlees Review, 2010). In its discussion of the relationship between the results of economic research and the design of policy, the report is of interest to economists and policy makers everywhere, not just in the United Kingdom. Income tax reform and design is an area where economic analysis and research can make – and indeed has made – significant contributions to policy formation.

Conclusion

Among all forms of taxation, the income tax has traditionally been the one that has been most surrounded by political controversy. To the individual taxpayer, the tax is much more visible than other forms of taxation, and it is one that more obviously affects his own economic situation. To the academic

economist, the income tax provides a fascinating area of application of his theoretical and empirical tools of analysis and it also gives him the opportunity to contribute to the public debate about tax policy. The trade-off between efficiency and equity concerns, which is basic to many aspects of economic policy, is nowhere more prominent than in the design of the income tax. The question of what weights one should assign to the benefits of redistribution versus the costs in efficiency is ultimately one that must be decided by the political system. What the economist can contribute to the political debate is a framework for systematic analysis and a sense of the empirical magnitudes involved both as regards incentives and redistribution.

Abstract

The term 'indicator' refers to a variable that is an imperfect representation of a social science concept. First, this article distinguishes different types of indicators (effect, causal, and composite indicators). Second, it describes the construction of measurement models, which are models that specify the links between latent variables (representations of social science concepts) and their indicators. Attention is given to the major questions that must be answered when formulating a measurement model. Third, this article reviews the properties of continuous and categorical indicators. Finally, the article provides an overview of the guidelines for developing and/or selecting indicators in empirical analyses.

Indicators and related terms (e.g., proxies, scales) refer to variables that are imperfect representation of social science concepts. The focus of this article is the treatment of indicators in social science research. It describes the construction of measurement models to link the latent variables that represent concepts to their indicators that contain measurement error. The article reviews the major questions that must be answered when formulating a measurement model. The properties of the indicators are the next topic. Finally, the article gives an overview of the guidelines to employ when developing or selecting indicators.

Concepts in the social sciences are often abstract. Current knowledge or data allow only imperfect empirical representations of them. Abstract ideas such as intelligence, the values of goods, individual attitudes, or social class are important to social science research and need to be empirically tracked even if the means of doing so are limited. 'Indicator' is a common term to refer to the variables that social scientists use to detect these concepts empirically. Other terms are *proxy variables*, *items*, *measures*, *scores*, *scales*, *indices*, or *observed variables*. Occasionally, some of the terms have a 'part–whole' relation where, for instance, a scale or an index might refer to the sum of items or the sum of indicators. But there is no complete consistency in these uses so that it is common for researchers to refer to a Likert scale even though it is a single item or an indicator. Furthermore, the frequency of the use of these terms varies by discipline. Economists, for example, regularly refer to proxy variables while educational testing psychologists frequently refer to items or scales. Regardless of the name, they all refer to a variable that is directly associated with a latent variable such that differences in the values of the latent variable mirror differences in the values of the indicator.

Latent variables are variables that represent concepts. There should be a separate latent variable for each dimension of a concept and a minimum of one indicator per latent variable. Indicators of latent variables are typically observed variables, but in special circumstances a latent variable might serve as an 'indicator' of another latent variable (e.g., higher-order factor analysis). The indicator's importance derives from what it reveals about the latent variable. The indicator informs about the magnitude of the latent variable across cases or overtime for the same cases. The key idea is that the indicator provides information on the latent variable. One might, for example, be interested in socioeconomic status (SES) of individuals where SES is defined as the overall standing of an individual in the social and economic stratification systems of a community and use a single latent variable to represent this overall standing. Income and education are two indicators of SES, but they do not fully capture SES. Or one could have a test designed to tap the anxiety levels of individuals, but the item or overall test score would not perfectly measure anxiety. So the use of the term 'indicator' and other related terms gives recognition to the fact that the variables social scientists often have to work with are not identical to their respective latent variables.

Measurement Strategies

When faced with latent variables for which there is no ideal measure, researchers typically follow one of three strategies: (1) ignore the latent variable, (2) include indicators but ignore their measurement errors, or (3) include indicators but take account of their measurement error. An example of strategy (1) is a study that is interested in the educational attainment of individuals. Suppose that the researcher recognizes that an individual's motivation or drive plays a role in educational attainment, but given the difficulty of measuring motivation she or he ignores it. The danger of this all too common decision is that the omitted latent variable is likely to bias the estimates of the impact of the other included explanatory variables. In the educational attainment empirical analysis, part of the effect attributed to say, parental educational attainment might actually be due to the unmeasured motivation variable.

In strategy (2) one could include an indicator of motivation but ignore its measurement error. In this case, the indicator for motivation allows one to partially control for motivation and estimate the impact of motivation, but because measurement error is ignored both the estimate of motivation and estimates for variables associated with motivation are likely to be biased. Contrary to conventional wisdom disregarding measurement error is not a conservative approach. In general, random measurement errors in two or more explanatory variables will not always lead to underestimates of effects of motivation or the effects of the other variables in the analysis (Bollen, 1989).

A natural question is whether one is better off including the indicator and ignoring the measurement error as in strategy (2) or ignoring the variable altogether as in strategy (1). Those researchers who have explored this question generally find that it is better to include an imperfect indicator than to ignore the latent variable altogether (Aigner, 1974; McCallum, 1972; Wickens, 1972).

Strategy (3), including indicators and taking account of their measurement errors, is generally the best choice. Here one could include indicators of motivation and control for the influence of the measurement error in these variables. This approach would halt the spread of bias due to omitting the latent motivation variable or treating the motivation indicators as if they were perfect measures. A requirement for taking account of the measurement error is the formulation of a measurement model.

Measurement Models

Measurement models refer to the implicit or explicit models that relate the latent variable to its indicators. Several basic questions require consideration prior to building a measurement model: (1) Are there *causal* or *effect indicators*? (2) Are there *multiple* or *single indicators* of the latent variable? (3) Is the latent variable continuous or noncontinuous? (4) Are the indicators continuous or noncontinuous? (5) Does more than one latent variable influence the indicator?

The first question concerns whether the indicators influence the latent variable (causal indicators) or whether the latent variable drives the indicators (effect indicators). The overwhelming majority of social science work on measurement has focused on effect indicators where the indicators depend on the latent variable. Sometimes these are called 'reflective indicators.' Differences in verbal ability, for instance, determine the differences in values for a test of verbal ability. Or an antitax attitude should determine the responses that an individual gives to a question on attitudes toward taxes. Effect indicators are implicitly assumed in factor analysis and in much of measurement theory in the social sciences.

Blalock (1964) called attention to causal indicators, in which the indicator influences the latent variable rather than the reverse. Some refer to these as 'formative indicators,' though this term is better reserved for composite indicators, a different type of indicator discussed below. Education and income of an individual, for instance, influence SES making these variables likely to be causal indicators. The amount that a child watches violent television shows, plays violent video games, or views violent movies are causal indicators of the latent variable of exposure to media violence. Often researchers do not consider that an indicator may be causal and treat all variables as effect indicators. This is not an inconsequential decision since causal and effect indicators have different properties and their incorrect classification can bias estimates from a model (Bollen and Lennox, 1991; Bollen and Bauldry, 2011). So a researcher needs to decide whether indicators are causal or effect indicators or some mixture of types.

The primary method for making this determination is performing mental experiments where the researcher imagines whether shifts in an indicator are likely to result in shifts in a latent variable as would occur with causal indicators or vice versa as would be the case for effect indicators. For instance, increases in time spent watching violent television shows increases the overall exposure to media violence. Increased overall exposure to media violence does not necessarily lead to increased watching of violent television. In some cases, empirical tests based on the presence or absence of vanishing tetrads can test for causal versus effect indicators (Bollen, 1989; Bollen and Ting, 2000). Tetrads refer to differences between the products of pairs of covariances among four random variables. Tetrads that equal zero are said to be vanishing tetrads. Models with effect indicators often imply vanishing tetrads that are not implied by models with causal indicators. These differences in vanishing tetrads are key to empirical tests.

Two complications arise when dealing with causal indicators. First, it is more challenging to specify an identified model with causal indicators. Identification is too complicated to cover here, however, suffice it to say that it is often easier to identify models with effect indicators than those with causal indicators. Second, causal indicators can be mistaken for composite (formative) indicators or covariates due to the fact that causal indicators, composite indicators, and covariates all affect latent variables. Bollen and Bauldry (2011) distinguish causal indicators as having conceptual unity and stable effects on the latent variable they measure across different outcomes of the latent variable. By contrast, composite indicators need not have conceptual unity, perfectly determine the 'latent variable' (i.e., there is no residual variance for the latent variable), and their effects on the latent variable may differ across outcomes of the latent variable. Covariates have similar properties to composite indicators, but they are not intended as indicators of a latent variable and generally do not perfectly determine the latent variable.

As an illustration of these differences, race and gender are common *covariates* that influence many different latent variables without being considered measures of those latent variables. A composite variable of childhood background effects might be formed as the weighted sum of *composite indicators* of single-headed household, recipient of welfare, record of juvenile delinquency, and frequency of moving. Finally, education, income, and occupational prestige could serve as *causal indicators* of SES.

The second characteristic of measurement models is whether there are multiple indicators of a latent variable or just one. Multiple indicators are generally preferable to single measures. In the case of effect indicators, multiple indicators are often essential in 'identifying' (permitting unique estimates of parameters in) the measurement model, are helpful in testing the number of latent variables underlying the measures, and enable assessments of the quality of the indicators. Multiple causal indicators can lead to a fuller description of the latent variable's core meaning. For instance, using education, occupational prestige, and income as causal indicators of SES provides a more comprehensive picture of SES than would income alone. In addition, leaving out causal indicators usually will bias the estimates of the effects of the remaining causal indicators on SES. So for both types of indicators it is better to have more rather than less.

The third and fourth distinctions from above are whether the latent variables and indicators are continuous or not. Latent

or indicator variables that are best thought of as approximating a variable that has infinite gradations of magnitude can be thought of as continuous. Indicators at best can approximate continuous variables since the limitation of measuring instruments will not permit infinite gradations. However, indicators approximate continuity in measurement to varying degrees. Population size, number of crimes, or counts of correct answers on a test are strictly speaking noncontinuous since the measures have interval units. However, in many situations, little harm is done in treating such indicators as if they were continuous. Alternatively, if one uses a three-point scale to measure an attitude, it is difficult to consider the indicator continuous even if the corresponding latent variable is continuous.

One source of confusion when considering whether a latent variable is continuous or not is that researchers sometimes confound the indicators' properties with those of the latent variable. Consider the situation of a survey question on abortion that asks whether the respondent supports or opposes a woman's right to an abortion. Though the response categories for the question might permit only two answers, this does not mean that the abortion attitude *latent variable* is a dichotomy. It seems far more likely that the latent attitude is continuous such that not everyone who agrees to the right to abortion has the same degree of support. Some might be just above a threshold on the continuous abortion attitude and this leads them to choose the support category whereas others might be way above the threshold when they give their support response. In this and related situations, the latent variable is continuous even though the design of the measure forces the responses into categories. The researcher needs to consider whether it makes sense to consider the latent variable as continuous or categorical without confounding the nature of the indicator with that of the latent variable.

Theoretically, it is possible to have any combination such as a continuous latent variable and noncontinuous indicators or a noncontinuous latent variable and noncontinuous indicators. In practice some combinations are far more frequent than others. Consider effect indicators first. Treating both the latent variable and its effect indicators as continuous is particularly common. A typical equation for a measurement model for this case is

$$y_j = \alpha_j + \lambda_{j1}\eta_1 + \varepsilon_j \qquad [1]$$

where y_j is the jth effect indicator that is approximately continuous and the right hand side of the equation includes an intercept (α_j), a factor loading coefficient (λ_{j1}) that gives the expected difference in the indicator for a one unit difference in the continuous latent variable (η_1), and the continuous disturbance (ε_j). The disturbance has a mean of zero and is uncorrelated with the latent variable. This model captures many factor analysis (Mulaik, 1972) and structural equation model formulations (Bollen, 1998), though factor analyses often deviate the observed variables from their mean so as to eliminate the intercept term.

An increasingly popular but less common formulation is to have a continuous latent variable with one or more noncontinuous indicators. With two exceptions, the same equation captures this situation. One is that a y_j^* replaces y_j where the y_j^* is the jth *latent* continuous indicator of the latent variable. The second difference is that there is an auxiliary measurement model that links the continuous y_j^* latent indicator to the noncontinuous observed indicator, y_j. For instance, if y_j is a dichotomous 0,1 variable the auxiliary equation might represent it as

$$y_j = \begin{cases} 1 & \text{if } y_j^* \geq 0 \\ 0 & \text{if } y_j^* < 0 \end{cases} \qquad [2]$$

An exact nonlinear function would link the continuous latent indicator to the observed noncontinuous effect indicator. This is easily generalized to ordinal and censored effect indicators. This formulation is common in structural equation models (Muthen, 1984). Item Response Theory (IRT) provides a related approach to having continuous latent variables and noncontinuous indicators (Lord, 1980; Hambleton and Swaminathan, 1985).

Less frequent are instances where both the latent variable and its effect indicators are categorical. For instance, one might have several informants who report whether the head of the household is receiving welfare or not. The latent variable is welfare status with only two categories: receiving or not. The informant indicators have the same two categories though each informant might make a classification error. Latent structure or latent class analysis (Lazarsfeld and Henry, 1968) provides a means to handle this situation. Other combinations such as a categorical latent variable in combination with continuous effect indicators or a mixture of continuous and noncontinuous effect indicators are also possible, though they are rare in practice.

Causal indicators are far less studied than effect indicators. However, incorporation of continuous and noncontinuous causal indicators in a model with a continuous latent variable is possible provided the latent variable has sufficient outcomes to permit model identification (Jöreskog and Goldberger, 1975). Perhaps the least studied case is that of having causal indicators (continuous or not) combined with a categorical latent variable.

A final consideration is whether more than one latent variable influences an effect indicator. It could be that two indicators derived from a questionnaire are from similarly worded questions such that the wording is a method latent variable that influences both items in addition to the substantive variable that they tap. Or indicators deriving from the same judge might share a common bias beyond their common dependence on the same latent substantive variable. It is also possible that two or more substantive latent variables help to determine the values of an indicator. For instance, a measure of the democracy of a political system might measure both democracy and the stability of the system. An indicator of depression might reflect both negative affect and sleep disorders. In these situations, the measurement model should allow two or more latent variables to affect the indicator. Generally researchers try to design indicators so that they primarily represent a single latent variable, but this is not always feasible.

Properties of Indicators

Properties of the indicators are useful to both current and future researchers who plan to use them. Among the two most important properties are the validity and the reliability of the

indicators. Validity and reliability are properties that have received their greatest attention in the case of measurement models with continuous latent variables and approximately continuous effect indicators. Indicator *validity* concerns whether the indicator really measures the latent variable it is supposed to measure. Construct validity, criterion validity, and content validity are types of validity that researchers sometimes examine. Construct validity, for instance, assesses whether the indicator is associated with other constructs that it is supposed to relate to and not associated with those that it should not. Criterion validity compares the indicator to some standard variable that it should be associated with if it is valid. Content validity examines whether the indicators are capturing the concept for which the latent variable stands. See Nunnally and Bernstein (1994) for further discussion.

Reliability focuses on the consistency or 'stability' of an indicator in its ability to capture the latent variable. It is distinct from validity in that one can have a reliable indicator that does not really measure the latent variable. A general definition of the reliability of an indicator is the proportion of the 'true' (latent variable) variance divided by the total indicator variance. A variety of statistics to estimate reliability exist. One of the most popular method to measure the reliability of several combined effect indicators is Cronbach's (1951) alpha. It also makes a number of assumptions that might be difficult to satisfy in practice. Alternative measures of reliability built from less restrictive assumptions also are available (Bollen, 1989).

IRT assumes a continuous latent trait and a categorical effect indicator, usually dichotomous or ordinal. IRT focuses on other properties of categorical items or indicators such as item discrimination and item difficulty (Hambleton and Swaminathan, 1985). IRT is similar to the traditional treatments of reliability and validity in that it too focuses on effect indicators. Latent class or latent structure analysis (Lazarsfeld and Henry, 1968) also deals with effect indicators. It applies when we have latent categorical variables with categorical indicators. The degree of classification error of the observed categorical variables provides information on the accuracy of the indicator. The combination of a latent categorical variable with continuous effect indicators are less extensively developed than are the cases of continuous latent variables with continuous or categorical effect indicators.

The measurement properties of causal indicators are less discussed. An important point is that use of the causal indicator assumes that it is the causal indicator that directly influences the latent variable. If the causal indicator itself contains measurement error, then this needs to be part of the measurement model.

Indicator Development and Selection

A salient component of indicator methodology is the development or the selection of indicators. The most critical and most neglected aspect of this task is providing a clear *theoretical definition* of the concept that a researcher seeks to measure. The theoretical definition assigns the meaning to the concept. It should explain in as simple of terms as possible what it is that is to be tracked by the indicators. A clear theoretical definition should identify the number of distinct aspects or *dimensions* of the concept. Each dimension requires a separate latent variable. Furthermore, the theoretical definition should clarify whether the latent variable is continuous or not. Each latent variable is ideally measured with several indicators.

Once a clear theoretical definition is in hand, the researcher collecting original data can design indicators that correspond to this definition. If only secondary data are available, the theoretical definition provides guidance in the selection of indicators. With the indicators selected to represent each latent variable, the next step is to decide whether each indicator is a causal or an effect indicator. That is, an investigator needs to decide whether the indicator influences or is influenced by the latent variable to which it corresponds.

Next, the researcher should construct a model summarizing the relation between the indicators and the latent variable(s). The model should take account of the continuous or noncontinuous nature of both the latent variable(s) and the indicators. Once the measurement model is constructed, a researcher can then explore ways of estimating it. If, for instance, both the latent variables and effect indicators are essentially continuous, then confirmatory factor analysis applies. After estimation, the researcher can assess the overall fit of the model and the properties of the indicators. This check might reveal that modifications to the model are required. It might be the case that some indicators prove faulty or the overall fit of the model might be poor, raising questions about the original specification. The analyst might then implement minor or major changes ranging from the introduction of additional parameters to the model to the formulation of quite a different model. The researcher would then estimate the new model and again assess its adequacy.

Summary

Indicators and related terms give recognition to the gap that exists between social science concepts and measures. During the last half of the twentieth and the first part of the twenty-first century, a variety of techniques and statistical models have been developed to enable researchers to study and to take account of the measurement error in the indicators. It is also possible to estimate relations between different latent variables while controlling for measurement error. Though the measurement models cover many situations, further development of techniques to handle some combinations of categorical and continuous latent variables and indicators is required. However, a far more serious problem is the prevalent practice by social scientists of ignoring measurement error in their indicators or ignoring altogether latent variables that are difficult to measure.

Indigeneity

Jeremy Beckett, University of Sydney, Pyrmont, NSW, Australia

Abstract

Indigenous peoples are the original inhabitants of lands that were subsequently occupied by new comers, in relation to whom they remain to some degree culturally different, and politically and economically inferior. Such situations are to be found in European settler colonies in the Americas, Australasia, and elsewhere, although the original inhabitants are not always recognized as indigenous. Since the mid-twentieth century, there has been local and international recognition of indigenous peoples, and a corresponding political mobilization, and cultural revival. Instances of these developments are included from Mexico and Australia.

Introduction

Indigeneity has as its literal meaning 'belonging to a place,' but in its current use it differentiates the original inhabitants of a territory from those with whom they now share it. Culturally, indigenous difference is defined in terms of not only adherence to tradition and a keeping of modernity at arm's length, but also as having an inferior and deprived status in the society of which they are a part. Conceptions of indigeneity are poised uneasily between these two sets of criteria, as political and economic objectives for either group may or may not be compatible. Settler colonialism, in which the original inhabitants have been displaced by latecomers, whether a majority or a minority, has given rise to many, although not all situations of indigeneity.

As it is experienced, and as understood by social scientists, indigenous difference has also been seen in terms of racial, ethnic, or class difference. Ethnicity is the term often applied to indigenous people in the discourse of multiculturalism, but it differs in having "a different relationship to national time and space" (Povinelli, 2002: p. 480). From around the middle of the twentieth century, the emphasis has shifted to the cultural, with revaluation of indigenous traditions, or acceptable elements of them, and recognition of the disadvantageous effects of settlement upon indigenous ways of living. At the same time, inspired in part by struggles against racism and colonialism elsewhere, indigenous groups have found the political and cultural space to make claims on their own account, to rearticulate fractured traditions, and even to reindigenize where these have been lost.

In the new millennium, indigenous or 'First' Peoples have, as Francesca Merlan insists (2009: p. 306), emerged as a construction, based on a kind of difference that, despite its diversity, is notionally shared vis-à-vis the rest of the world (Niezen, 2000). Although rarely powerful at the level of the nation states in which they are situated, they have belatedly established a presence at the United Nations (UN).

After a brief historical review, mainly of the European settler colonies, this article will focus on the years following World War 2 up to the present. It is suggested that any discussion of indigeneity as a global category has to be read from the bottom up against the innumerable local instances, where indigenous identities may be embedded in other kinds of relations, political, economic, and cultural. A distinction must also be made in terms of the number of the indigenous sector vis-à-vis the nonindigenous, the capacity of national governments to control the indigenous sector, combined with their vulnerability to international opinion.

While gains have been made on the global, and certain local stages, economic globalization and technological change have subjected surviving indigenous resources to a new round of pressures. However, resistance to the Norwegian government's plans to build a new hydroelectric project, induced the Saami to identify as indigenous, although they had not previously been identified as such (Paine, 1982).

Imperial Beginnings

The contemporary notion of indigeneity has its beginnings in the European colonization of the New World, and the appearance of settlers intending to make their homes in places that were already inhabited. It can be conveniently dated from Columbus's landfall in the Americas in 1492, although events subsequently followed a similar course in Australasia, parts of Africa, and some Pacific islands. Settler societies commonly identified indigenous peoples using generic terms such as 'natives,' in the Americas 'indians,' aborigines, kaffirs, kanakas – not the names by which the subjects had hitherto identified themselves – thus defining them in relation to the settlers rather than recognizing differences that might have existed among themselves. Settler colonization entailed the subjugation of the indigenous population, followed by the extraction of precious metals and the establishment of plantations and farms. These often entailed the expropriation and displacement of the indigenous population. In some places, they were required to work for the colonists; in others, they were consigned to the margins of the emerging settler society, which had little use for them or their land. In some colonies, these arrangements took the form of formal treaties, not always observed; in others, the indigenous groups were confined to church missions or government settlements.

In the heyday of settler colonialism, indigenous populations were of lower status, an opinion reinforced by theologians, philosophers, and scientists: not merely different, but as inherently inferior, or in the words of early anthropology,

'primitive.' The fact that they were not, unlike the colonists, Christians, provided the opportunity for missionaries to 'convert the heathen,' although rarely with certainty that their flocks had become 'truly Christian.'

Indigenous Peoples in Settler States

Starting with the American war of independence from Britain in the eighteenth century, followed by the revolt of Spain's colonies, most of the world's settler colonies had either won or, as in the case of Canada, Australia, and New Zealand, been granted independence from the metropolitan power by the turn of the twentieth century. (French and Italian settlers were driven out of North Africa mid-century, leaving only South Africa until the end of the millennium.)

Often enough, this independence gave the Creole element greater license to exploit or dispossess the indigenous population. However, while some remained setter states, many imagined themselves as nations (Anderson, 1991: Ch 4), whether a nation of citizens, which at least in principle if not in practice, included indigenous people, or a system of stratification. In the latter case, indigenous difference was formally recognized, in law or treaty, often with a special government agency having charge of their affairs. As such, they were consigned to a peripheral role in national affairs or excluded altogether.

Given the dislocation and the social and cultural disruption suffered by indigenous populations under the impact of settler colonialism, the original boundaries between indigenous groups, and between indigenous and nonindigenous were often disrupted. There emerged categories whose status was ambiguous, hybrid, or otherwise undefined, with terms such as mestizo, ladino, half breed, half caste, etc. Whether or not recognized in national ideology, such groups may now constitute a majority of the population, but only some will be classified as indigenous; in other classifications, anyone of indigenous descent is classified as indigenous.

Such definitions, or the lack of them, become significant when national governments formulate and implement policies specifically for the government and policing of indigenous minorities. Initially, the solution was often to perpetuate the regimes of the departing colonial administration, with bureaucracies or missions taking responsibility for 'native affairs,' whether under the guise of 'protection' of groups who seemed to be dying out, or controlling the behavior of the survivors. Later there might be attempts to 'assimilate' or 'integrate' indigenous groups, eliminating cultural differences, so that they might gradually become citizens, notwithstanding physical or racial difference. Finally, in the postcolonial period (The term 'postcolonial' has been used mainly to refer to the dissolution of the European colonies, and the new states that emerged. Ironically, the European settler colonies have retained at least some of the features of colonialism, even though they might like to shed the colonial reproach in their relations with the new states.), there might be attempts to recognize indigenous difference, or some version of it, as acceptable to the dominant group.

Government programs for indigenous peoples depend on the resources available, the number of the indigenous population as a proportion of the total population, as well as the resources that the indigenous group still occupy or can claim. According to official estimates (These figures are not all based on the same sets of criteria. As reproduced here, they simply indicate the number of indigenous people a state recognizes as living within its borders.), the indigenous population exceeds 40% in the Andean republics and Guatemala, and ranges between 5 and 20% in New Zealand, Chile, Venezuela, Mexico, Panama, and Nicaragua, and between 1 and 4% in Australia, the United States, Canada, Colombia, Norway, Malaysia, and the Philippines (The Philippines has lately declared certain groups living in Mountain Province as 'indigenous' partly it seems because they were so identified during the American colonial period. Muslim groups living in the south of the archipelago are not classified as indigenous.). The percentage is even smaller for Brazil, Sweden, Russia, and Japan.

However, the size of an indigenous population is no guide to its visibility on the national and global arena. In the second half the of twentieth century and in the new millennium, liberal and left opinion – although not necessarily a majority of the nonindigenous populations – has formulated alternative views on the rights and entitlements of indigenous people, in particular and in general. International bodies including the UN and numerous nongovernment organizations (NGOs) have pressured national governments. This climate has at least intermittently created a space for indigenous mobilization, which governments variously attempt to channel or contain. What happens varies according to the relative powers of indigenous groups, the governments who rule them, and global bodies such as the UN and various NGOs.

Indigenous Peoples in National and Global Perspective

The old colonialist formulation of indigenous peoples as a general category, overriding the particular ways in which they were identified by themselves or local others, underwent a transformation in the mid-twentieth century and into the new millennium, with the idea that all such people were entitled to political, economic, and cultural rights, which had all too often been denied in recent history and were still under threat. Colonial and national governments had in earlier years been left to deal with their indigenous peoples as they thought fit, whereas international bodies and eventually the UN came to provide an arena in which such matters might be raised.

In the context of the Cold War, and the replacement of the old imperial domains by nonaligned new nations, 'colonial attitudes' and racial discrimination became reproaches that most national governments preferred to avoid. The new medium of television transformed what were once domestic issues such as the African-American civil rights movement in the United States or the Bantu struggle against apartheid in South Africa into global dramas, on which the world could pass judgment and which they could relate their to own situations.

The UN made its Declaration of Human Rights in 1948, and this provided the milieu in which in the years that followed, the rights of indigenous people could become an exclusive agenda, leading to the establishment of a Working Group, and in 1993 to the submission of a draft declaration, which would eventually come before the General Assembly. At the 1992 UN Conference on Human Rights in Vienna, where racism was emerging as an issue, it was agreed to appoint a Special Rapporteur on indigenous peoples. Important in this process was the participation of indigenous peoples, with or without the backing of their national governments, whose travel was funded by the UN, the first such occasion being the UN NGO Conference on Discrimination against Indigenous Populations in 1977. Negotiations with national governments followed, and the final Declaration did not come before the UN until 2007 (Eide, 2009: p. 32).

The UN was but one of the opportunities for indigenous people to air their needs and grievance to the world at large. To mention a few key dates – 1971 World Council of Churches' conference on the Liberation of the Indian, the 1975 convening of the World Council of Indigenous Peoples in British Columbia, the meeting of the same body in Australia in 1981, and the World Trade Organization meetings in Cancun, Mexico in 2003. One would have to add to this list, numerous NGOs such as Cultural Survival, Survival International, and the International Working Group for Indigenous Affairs. This has also been a time when various indigenous groups and spokespersons have come together to share experiences with one another and with nonindigenous sympathizers.

It should be noted that in varying degrees, indigenous activism received nonindigenous support from national as well as international intelligentsias, moved by new approaches to social justice, religion, the environment, and changing notions of national identity.

The UN Declaration included some 40 articles, which, briefly summarized, called upon governments to protect indigenous peoples from any kind of discrimination, enable them to practice and restore their cultures, protect their land and resources from encroachment, facilitate the return of lands usurped, and achieve self-determination. In the event, the Declaration received overwhelming support from the General Assembly. It was, however, opposed by Australia, Canada, New Zealand, and the United States, because of the implications of the return of land and the possible implications of self-determination. However, the declaration was 'nonbinding' on the governments who approved it, and they all subsequently gave their support. It is difficult to assess to what extent it has affected the practices of the governments with whom, in most cases, indigenous peoples have still finally to deal.

Merlan in her overview 'Indigeneity, Local, and Global' (2009) argues that, "the impetus for internationalisation of indigeneity has come from liberal democratic 'political cultures'" "the impetus for internationalisation of indigeneity has come from liberal democratic" (p. 304), such as Australia, New Zealand, Canada, the United States, and the Scandinavian countries, whose Lappish population were renamed Saami following their reidentification as indigenous in the 1970s. She later suggests that the "volatile and often authoritarian regimes of Latin America and elsewhere have not provided such a favourable climate for the accommodation of indigenous aspirations." To argue this, however, is to ignore recent developments in many parts of Latin America (Stephen, 1997: pp. 4–5). Moreover, though many of Latin America's governments have been 'volatile,' this does not apply to Mexico, which has seen an orderly succession of single-term presidents since 1920. While Merlan may be right to differentiate the liberal democracies Australia, Canada, the United States, and New Zealand from those of Latin America, this approach weighs her analysis in favor of the center, at the expense of the view from below, where the action often is. This raises not only the question of how strong central government is, and how much space it leaves for local mobilization, but the relative numbers of indigenous and nonindigenous involved. As indicated earlier, the numbers of people recognized as indigenous in most of the Latin American states far exceed that of the liberal democracies, except for New Zealand, where the Maori have long been integrated in national and economic affairs. Moreover, in Latin America they are often concentrated in particular regions, and to the extent that central government has to work through local alliances – whether *caciques* or parties – so that there can be some measure of local empowerment, whether the center wants it or not (cf Rubin, 1996). By comparison, in Australia, Canada, and the United States, indigenous people rarely have much influence even on local events, and even when their affairs are broadcast in the national media, these are dealt with by specialized arms of government. In the discussion that follows, Australia and Mexico are taken, not as prototypical of indigeneity in general, but as case studies that reveal some of its features as well as some of its diversities.

Indigenous Mobilization and Political Process: Mexico and Australia

Charles Hale, in commenting on Merlan has argued that while "Liberal democracies have surely developed their own recognition projects for indigenous peoples….this should not negate the central role of collective indigenous agency and self making…" (Hale, 2009: p. 323). A Latin Americanist himself has pointed up the greater role of indigenous mobilization in these countries than in the Liberal democracies, where the tendency has been top-down. With the exception of New Zealand, it has been possible for the national and regional governments to separate off indigenous affairs from other branches of government, since the indigenes in question, being few in number, have had little in the way of political leverage.

In much of Latin America, there has been a long tradition of indigenous activism, although indigeneity has often been left implicit, in favor of class, regional, or populist party alignments. Marxism, however, attracted national and – particularly from the United States – international repression, and Warren and Jackson suggest that during the 1970s and 1980s, "mobilizing switched to the new discourses of collective rights and cultural diversity." They note that in 16 Latin American countries "constitutional reforms have challenged the dominant imaginary of the nation by redefining the status of indigenous communities and transforming the meaning of citizenship"

(2002: p. 13). However, Mexico is not among the countries on which they base this claim, and it appears to be somewhat different.

Mexico classifies some 15% of population as indigenous, with use of one of the six indigenous languages among the criteria. The nation had a long history of recognizing the indigenous, to the extent of celebrating the achievements of the pre-Columbian civilizations, notably in the Anthropological Museum in Mexico City, although this did not necessarily benefit their living descendants. In earlier years, the national government also promulgated a doctrine of *mestizaje*, according to which indigenous difference would in due course be absorbed into the nation. Among the tasks of the National Indigenist Institute was the setting up of schools in which indigenous children could learn Spanish. This assimilationist approach came under increasing criticism from scholars and students of the generation of the 1960s and after (Lomnitz, 2001). In 1992, the Mexican state revised its constitution to declare itself a pluricultural nation. It was also among those nations that endorsed the UN Declaration.

The relations between Mexican government and its indigenous peoples are more complex, however. Following the revolution of 1910–20, indigenous and other peasant groups had benefited by the land distributions in the 1930s, but national politics from that time, and with only few interruptions up to the present, have been dominated by a single ruling party (Partito Revolucionario Institucional (PRI)), which in complex and variable ways mediated between the center, local power holders, and the populace at large, often to the disadvantage of the last.

Mexico's indigenous population is concentrated in the country's southwest. None of the six ethnolinguistic groups mobilizes as a bloc, and locally they have often been divided by a class aligned with the center, but going back to the nineteenth century, local groups have played a significant part in local politics, sometimes allied with nonindigenous parties, sometimes on their own account. Rubin, in his study of Juchitán, a town in the Isthmus of Tehuantepec, emphasizes that nation and regime exist not only outside of the town and Zapotec culture, but in the very fabric of local discourse and institutions as well (Rubin, 1996: p. 25). Rubin's study is focused on the local Coalition of Workers, Peasants, and Students of the Isthmus (COCEI), which in the 1970s and the 1980s cut across a local indigenous elite, and for a decade dominated local government. Although indigeneity was omitted from its title, the confederation "successfully appropriated Zapotec culture – including its elaboration and leadership – for a poor people's movement. This ethnic appropriation was a crucial ingredient in COCEI's success. COCEI's claim to Zapotec ethnicity … made available for radical politics a common language, a remembered history, dense market and ritual network, and abundant artistic and cultural representation that reconfigured cultural boundaries between 'popular' and high culture" (1997: pp. 42–43). In somewhat similar terms, Howard Campbell argues that, "Rather than opposing ethnicity and class, we need to examine their interplay … by abandoning this artificial division, we can understand how ethnicity is simultaneously a weapon against outsiders and a contested terrain of class interests within indigenous communities" (Campbell et al., 1993: p. 216). Although COCEI at times suffered violent reprisals from the national government, they could also enter into agreement, for example, during the *sexenio* of President Salinas (Rubin, 1996: p. 190). However, the Salinas presidency ushered in a neoliberal economy, including the North American Free Trade Agreement, and an impoverishment of the rural sector (Gledhill, nd).

While COCEI was mostly able to avoid direct confrontation with government, the very name of Chiapas-based Zapatista Liberation Army (Ejército Zapatista de Liberación Nacional (EZLN)), which emerged in 1994, suggested a more radical distancing from central government, and it was met at times by violent reprisals. Contrary to Warren and Jackson's generalization, it is identifiable as Marxist by the internationally diffused pronouncements of its nonindigenous leader, Subcomandante Marcos. The identification with the agrarian hero of the 1910–20 revolution, coinciding with land invasions, appeals to a broader constituency. Gledhill does not deny that "the cultural politics of indigenous identity has salience in the Selva. What needs to be stressed, however – given the diverse origins of those living in the Selva (Stephen, 1997: pp. 7–9) – is that it is a new cultural politics that is reappraising culture history and identity in the light of discourses on human rights" (nd: p. 24). Gledhill continues, "The strength of the Zapatista version of indigenous rights politics lies in its creative qualities and ability to engage universal values." This is "a twentieth century innovation" (Gledhill, nd: p. 24). One can add that its considerable international appeal – the news reached the world at large as soon as it did Mexico City – was almost certainly enhanced by the fact that it seemed to be an indigenous movement, and, following military repression, its retreat into the Lacandón Jungle.

Australian and North American governments have not experienced insurrectionary challenges to their authority in recent times – although there have been symbolic displays recalling such events. Dealing with much smaller indigenous populations, and being wealthier countries, they have been able to contain the indigenous problem through legal and economic means, seemingly approving in general terms the global indigenous rights movement, funding delegations to international conferences and festivals, but keeping it at arm's length when forming policy.

To turn to the case of Australia, the Aborigines have in the last 50 years been able to move from a position of virtual disempowerment, to a position of formal recognition in terms of cultural difference, but increasing economic and administrative dependence on government. This has left them collectively unequal vis-à-vis the majority population (Austin-Broos, 2011: pp. 9–12). Mobilization began in the 1960s and 1970s as a mainly urban 'protest movement.' It took as its model the African-American Black Power movement of the period, only later connecting with Native American Red Power, and other indigenous movements. Among the first such events was a 'Freedom Ride,' exposing widespread discrimination against Aboriginal people in country towns. Reversing the deference characteristic of the previous generation of spokespersons, many of whom had been nurtured by Christian churches, they communicated to the rest of Australia anger and alienation in deliberately confronting words. Taking advantage of the television cameras to stage what

Paine has called an 'ethnodrama,' one such gesture consisted of the 'Aboriginal Embassy,' a cluster of tents and a camp fire on the lawn of Parliament House, as a reminder of the conditions under which many Aboriginal people still lived (Lothian, 2004). The period saw increasing concern about the situation of indigenous people in a prosperous Australia, with liberal scholars as well as the political left drawing attention to discrimination and deprivation, which to many looked uncomfortably like the remnants of colonialism in a postcolonial world.

By degrees, the Federal government took nationwide responsibility for what became known as 'Aboriginal Affairs,' replacing or overriding state governments and church missions. The policies of the 1970s through the 1990s were intended to recognize and respect Aboriginal difference. One prime minister took personal charge of land rights; another made a formal apology for the removal of children under the former assimilation policy.

Although still to be heard, the urban mobilization became secondary to developments in Northern and Central Australia. Although the official definition of Aboriginal included anyone of Aboriginal decent, the difference, physical and cultural, of those living remote from the urban centers seemed more apparent to government and the country at large. A group of Aboriginal pastoral workers had struck for higher wages in the mid-1960s, but when government legislated for equal, the employers' response was to mechanize the industry in such a way as to deprive Aborigines of their main source of employment, leaving them dependant on welfare. Thereafter, the main form of political action was in relation to land rights.

Foremost among the claims of the indigenous mobilization has been for return of at least some of the land that settlement had originally taken from them without any recognition of prior ownership. Partly through government, and partly through the activism of nonindigenous lawyers, appealing to a sympathetic judiciary, it became possible for indigenous groups to claim certain categories of land, through a legal process, requiring their 'elders' to testify to connection from before settlement, but at the same time establish boundaries separating them from other Aboriginal groups. Processes, often prolonged over years and requiring the services of lawyers and anthropologists, are funded by government. Often at the time of reclaiming it, the land returned had no value to nonindigenous interests, but in recent years has proved to have minerals, which industry now wants to exploit. Its offers of royalties and often of jobs in return for access, may be opposed by the owners, but may also divide them along new lines.

Aboriginal Australians had only been able to vote since 1962, and as subsequent events proved, their numbers were rarely sufficient to affect the outcome of a contest in the nation at large, or even one of the states. Government instead set up indigenous representative bodies, notionally to meet the demand for self-determination. Established in 1990, *The Aboriginal and Torres Strait Islander Commission* was the first attempt to surrender a measure of policy-making power to indigenous people, ahead of Norway's Saami Parliament in 1989 and Canada's Nunavut in 1999. However, in 2004, the body was dissolved (Richardson, 2004). The attempt to run a body for the whole of indigenous Australia, disregarding the diversities, was probably a mistake. The need for executive office holders with a degree of sophistication tended to favor urban Aborigines, who were not necessarily in sympathy with these in the remote regions. Subsequently, the government has limited decision making powers mainly to local communities. 'Consultation' preferably with 'elders' is nevertheless an important feature of government practice, albeit often beyond the capacity of busy bureaucrats to achieve (Lea, 2008). With customary practices failing among an increasingly young population, one may wonder whether cultural difference may recede, revealing a stark inequality (Beckett, 2010: p. 43; Austin-Broos, 2011).

In the event, the national government's assumption of responsibility for Aboriginal affairs has committed it to an ever-expanding budget, since it coincided with the closure of the kinds of occupations in which indigenous people had previously made their living (albeit underpaid), while a return to traditional hunting and gathering was no longer an option. At the same time, governments had pledged to 'close the gap' between indigenous and other Australians in the areas of health, housing, education, and incarceration rates. This has left a large part of the indigenous population dependent on welfare or some other government services – a condition that some critics have called welfare colonialism – and that leaves them vulnerable to bureaucratic intervention in their domestic lives.

For a small but growing number of educated indigenous people, there is a parallel dependency on bureaucratic jobs in some branch of Aboriginal affairs. Under such circumstances, the mobilization of this sector, if not quite controlled by government, is diverted along channels laid down by government service.

In addition to the bureaucratic jobs available to school leavers, government has brought into being a small indigenous intelligentsia, including academics. Various arms of government have also sponsored indigenous artists and performers, sending them with their creations to international events. It is mainly from this sector that ideas of a pan- rather than local Aboriginality, its qualities, rights, and future, are articulated. Likewise, it is from this sector that the media, academe, and government seek opinion on policy matters, although there is considerable disagreement on the social and economic viability not only of the remote community, but also of the desirability of employment in the mainstream economy (Langton, 2010).

The preceding thumbnail sketches of the situation of some indigenous people in Mexico and Australia reveal substantial differences, not merely the relative sizes of the two country's indigenous populations and the resources available to the two governments to assist them if they wish to, but the differing emphases on indigeneity, as compared to other forms of engagement with the encompassing society. Australia's Aborigines base their appeal largely on their indigenous status, and their nonindigenous support base seems to view them in the same way, whereas the Mexican groups discussed above seem often to leave their indigeneity implicit – a basis perhaps for internal solidarity – but situate themselves in terms of class (as in the case of COCEI) or national and Latin America-wide revolutionary traditions (as in the case of the Zapatistas). Both groups have been ready to negotiate with other dissident parties within Mexican political life, and occasionally reach agreement with the central government, as these bodies are with them.

Indigeneity, Indigenism, and Reindigenization

The idea of the indigenous evokes in the Western mind people occupying the places they have 'since time immemorial,' passing on to each generation traditional knowledge of pursuits that keep them close to nature, as well as a close community life and forms of spirituality that are in tune with this. The history of indigenous peoples has in greater or lesser degree been characterized by encroachments on this space, and if they can no longer disengage, their lives become hostage to the schemes of the majority. However, some of these groups have become adroit at keeping the encroaching world at arm's length enabling them to preserve vestiges of an indigenous space, perhaps grounded in a distinctive mode of livelihood, relatedness, or religious practice, albeit distorted by the engagement.

The renewed valuation of indigenous cultures – or elements of them on the part of the nonindigenous sector – has given their bearers the space to identify or reidentify, but as Li argues, "as a positioning that draws upon historically segmented practices, landscapes, and repertoires of meaning, and emerges through patterns of engagement and struggle" (Li, 2000: p. 151). With the passing of time, not all such things may still be accessible, nor in the contemporary situation may they be practicable or desirable. Those that are accessible may carry a different kind of baggage in the contemporary situation, becoming reified in the process of 'positioning.' Some practices marked as indigenous, may, at least when compared with earlier accounts, prove to be modeled after prior practices, rather than as continuations of them, and some are simply reinvented.

The renewed acceptance of indigenous cultures has given rise to an ironic rapprochement that Sider and Dombrowski (2001) have called indigenism, referring to the political and the author would add cultural middle ground, which arises out of the engagement of indigenous and nonindigenous meanings, in which understandings are sometimes reached, but sometimes left contested or unresolved. Thus, spirituality – a common trope of indigenism – may be expressed in the form of Christianity, into which a people may have been converted in colonial times, but that has been incorporated into the life of a community so that it can be seen as significantly different.

Arts and crafts are areas where indigenous people are able and increasingly encouraged to practice, by state and commercial sponsorship with creations often modeled after traditional forms rather than replicating them, and directed at the international high art market, as in the case of Aboriginal Western Desert art (Myers, 2002: pp. 252–254), or tourism. National museums both collect and display indigenous creations, and send them overseas. Whether state sponsored or not, these developments may amount to a moment of reindigenization, in the sense of a self-conscious attempt to revive tradition in particular areas of life, if not the whole.

Scholarly Studies of Indigenous Peoples

The discipline of anthropology emerged in the wake of European colonization, as a study of the peoples who had been conquered and their lands exploited and settled by others. The original aim of the research was to document the societies and cultures of the conquered and displaced – 'before it was too late' – which is to say before depopulation or modernity took what was believed to be their inevitable toll. Although responding to newer trends in anthropology, some studies remain of this kind.

However, with the recovery of indigenous populations, anthropology turned its efforts to advising governments on how surviving indigenous groups should be treated. In some countries, national anthropologies emerged, which started with the assumption that indigenous groups were conationals, but while Mexican anthropology of the *indigenismo* period involved forging citizenship "by indigenising modernity and modernizing the Indians" (Lomnitz, 2001: pp. 228–262), Australia in the same period focused on the modernizing agenda, only later coming to some tokenistic idea of indigenizing the nation.

Other anthropologists, along with ethnohistorians, have maintained distance from government in monitoring the impact of settlement on indigenous peoples (Wolf, 1982). These studies, too numerous to mention individually, are usually grounded in the experience of a local community, although attention has recently shifted to the situation of indigenous peoples living in urban environments, away from their home communities. Anthropologists have also used their local knowledge to act as advocates in processes for the recovery, of land, and pursuing cases of racial discrimination.

Studies at the level of the nation state have been rather the province of historians, political scientists, and lawyers, some of whom have also worked comparatively, and in relations between indigenous peoples and the UN. Almost alone among anthropologists, Ronald Niezen has attempted an overview of indigeneity in the human rights framework, although Charters and Stavenhagen have edited a collection detailing the events leading up to the World Decoration on Human Rights (2009).

Abstract

This article will explore child welfare practice from an Indigenous perspective. In the article, we begin by centering Indigenous ways of caring for our children. We also provide an overview of how state-controlled jurisdiction over Indigenous children had intergenerational and devastating effects of legislation and policies on Indigenous families. Finally, we review how Indigenous peoples are reclaiming jurisdiction to deliver their own distinct methods of child and family services, in an effort to reclaim, regenerate, and strengthen Indigenous child well-being in British Columbia, Canada.

Introduction

This article explores child welfare practice from an Indigenous perspective. Both authors have personal and professional experience within Indigenous child welfare. Both authors have been instrumental in contributing, developing, and implementing Indigenous child welfare courses and programs at the University of Victoria, British Columbia, Canada.

This article is organized in three sections. Section one provides an introduction to Indigenous ways of caring for our children. Section two provides an overview of state control and jurisdiction over Indigenous children and the devastating effects of legislation and policies on Indigenous families, communities, and nations. Finally, section three examines ways in which Indigenous peoples are reclaiming jurisdiction over ways in which our people deliver their child and family services, in an effort to building healthy individuals, healthy communities.

Traditional First Nations Child Raising

(Throughout this article, we will use terminology of First Nations, Aboriginal, and Indigenous interchangeably depending on what we are speaking to. Many communities in Canada refer to themselves as First Nations people. Many other communities and people refer to themselves as Indigenous people and finally, Aboriginal, is terminology defined by the state.) Before settler contact, Indigenous nations ('Nations' is closely linked to the modern European concept of a 'state.' For Indigenous people, decision-making structure and methods are resolved within Indigenous sovereign states/nation.) were responsible for their own child welfare, and every culture dealt with their child-raising practices differently. There was recognition that children belonged to the community, and that children were the most precious people of the community. For many Indigenous nations, the old people and/or elders sustained and lived traditional and ceremonial practices that strengthened and enhanced the well-being of children and families. For example, rites of passage rituals involved practices that honored all stages of life and in this practice; family members such as aunts, grandmothers, and traditional teachers were involved in raising children. Rites of passage have been important for children, because these not only acknowledge varying life stages, but also the child learns who his or her caregivers are and knows that these caregivers will be nurturing and will provide support throughout their life. Another cultural practice important for the nurturing of Indigenous children and families include learning about Indigenous ceremony. In this, learning important ceremonies and rituals were done through storytelling. In this practice, children learned not only about different forms of ceremonial practices, but children also learned about their histories, landscapes, relations to animals, about other Indigenous communities, and about natural resources that sustained their way of life. This way of life and cultural practices were and are Indigenous knowledge, philosophies, and praxes once utilized to enhance the well-being of children and families.

Ceremonies were and are methods that encapsulate Indigenous living. Hence, ceremony is a way that our people view Indigenous law and policy. As Indigenous peoples, our belief is that our inherent rights, responsibilities, and laws flow from natural laws of what we refer to as inherent and from the Creator. Inherent knowledge or rights for our people instill our sense of belonging, connectedness to the earth and the responsibilities that we have to care for the earth. Importantly, in knowing ceremony and rights of passage, we understand the importance of connecting natural laws to our social responsibilities to take care of our children, families, and communities. In presettler times, ceremony and inherent knowledge was a method practiced by Indigenous peoples to care 'holistically' for children, families, and communities. Prior to settler contact, cultural practices, ceremonies, and rituals strengthened families and the caregiving of children, now known as child welfare.

Commonalities for Indigenous Approaches to Caring for Children

Prior to settler contact in Canada, and perhaps for other Indigenous peoples throughout the world, children were and are viewed as precious and the heart of communities. In this, there were common practices about caring for children that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28042-2

were nonintrusive to the family and community. For example, if a family were experiencing difficulties in raising their child, another family member would intervene and raise the child. In doing so, the 'other' family members who would intervene, would care for the children and this was done to provide space and time for parents to address their issues. For many Aboriginal nations, the first born was always raised by their grandmother and not by the 'nuclear' parent. In other situations, ceremony was utilized as a practice method to provide support to the family in need. Ceremony is a method that connects the family to all aspects of their being, such as their spiritual, physical, emotional, and mental state. The belief here is that when we collectively look after all aspects of our being, families recognize where there is 'unbalance' and also can see 'issues' they may need to work on. Traditionally, Aboriginal peoples in Canada have a broad definition of family membership and our children were cared for and raised by the extended family.

Storytelling has also been an important practice historically. Children learned the values of respect, honor, love, sharing through stories. They learned how to act in the world around them. Thomas and Green (2009) remind us that stories provided children with the skills needed to survive. "Traditionally storytelling was the primary source of educating our children. Our children were considered gifts from the Creator and, as such, were protected by all in our communities through stories" (p. 101).

Interruptions for Indigenous Child Caring

Disruptions in Indigenous family life in Canada began shortly after contact with European people. During early contact times, the relationships between European and Indigenous peoples of Canada were one of respect. However, over the years and due to development of lands for economic expansions, these relationships began to deteriorate. Relationships succumbed to the notion of 'power over' by the Canadian government toward Indigenous people. This power difference is described historically as the 'protection' phase of relations between settler Canadians and Aboriginal people. One of the earliest documented legislation intended to 'protect' Indigenous peoples is the Royal Proclamation of 1763. The *Royal Proclamation* (The *Royal Proclamation* was issued by King George III in 1763 to officially claim British territory in North America after Britain won the Seven Years' War over the French.) is a document that sought to protect Aboriginal (Throughout this article, we will use terms interchangeably. Indigenous is a term used by international group of Indigenous peoples. Aboriginal is a term used by government and Indian is a term within the Indian Act. Native is also used to describe a group characteristic of indigeneity.) people by providing instructions for European settlement of Aboriginal territories in what is now North America. The Royal Proclamation explicitly states that Aboriginal title has existed and continues to exist, and that all land would be considered Aboriginal land until ceded by what is now known as 'treaty.' The Proclamation provided the first policy preventing individual settlers from claiming land from Aboriginal occupants. The Royal Proclamation further sets out that only the Crown (Canada) can purchase land from Aboriginal people. By way of this law, the concept of the Crown's 'fiduciary' (One who holds anything in trust, or who holds a position of trust or confidence with respect to someone else.) responsibility with Indigenous people was set in motion, which continues to be in effect today. The Proclamation and its fiduciary responsibilities began to set the framework for the relationship between Indigenous people and Canada. This imposed relationship also affected how Indigenous people related to and learned about land teachings, and in turn affected cultural teachings and practices for Indigenous families.

Many more laws and policies emerged in a manner that continued to confine and control an Indigenous way of being. One such act that subjugated and oppressed Aboriginal people was *the Indian Act*, federal legislation passed in Canada in 1876. *The Indian Act* collected all "previous legislation pertaining to Indians into a body of law comprising over a hundred sections" (Lawrence, 2004: p. 33). The Indian Act defines who is Indigenous and who is not, according to the federal government. This act also articulated a reserve system where Indigenous peoples would reside and specified policies on how Indigenous peoples would be governed. This *act* is still in place today. Lawrence (2004) talks of the lingering effects of the 'Indian Act' and its policies:

> The Indian Act is much more than a body of laws that for over a century has controlled every aspect of status Indian life, it provides a conceptual framework that has organized contemporary First Nations life in ways that have been almost entirely naturalized, and that governs ways of thinking about Native identity.
>
> p. 34

Ormiston (2010) also contends that this act of colonialism intends to force the "colonized group into dominant society; adopting policies that suppress … transform or destroy Native values … orientations and way of life … manipulation and management of the colonized … justified by an ideology of racism" (p. 2).

Within the Indian Act, the goal of Canada was to eliminate traditional teachings, values, and significant cultural ceremonies through the banning of the Potlatch, Longhouse, and Sundance ceremonies as well as traditional governance systems. Cultural knowledge, philosophies, and practices were all outlawed as they provided a threatening opportunity for First Nations people to share their history and ways of doing, knowing, being into the future (Thomas, 2005: pp. 244–245). The federal government exercised jurisdiction and control over Indigenous peoples in Canada.

Affects of Colonial Practices

Resulting from colonial governing systems, Indigenous peoples were deemed to be inferior and uncivilized. Nowhere is this more evident than through the creation of residential schools, which resumed the federal government's role of 'protecting the child.' The government of Canada also sought to 'civilize' and assimilate Aboriginal people through residential schools.

Beginning in the late 1800s, the government and the church's attitude was that European culture was superior to Native cultures. Therefore, every First Nation's child was deemed to be in need of protection and it became compulsory in 1880 for First Nations children to attend residential schools (Powderface, 1984). Children as young as 5 years of age were removed from their families and communities for 10 months of the year or longer. In residential school, children were prevented from speaking their languages and taught to reject their traditional lifestyle. As Harold Cardinal (1999) wrote: "These schools were nothing less than state sponsored programs of cultural genocide aimed at Indian First Nations. Residential schools were an integral component of a systematic, intergenerational, state planned program of brainwashing aimed at removing the 'Indian' from the minds and souls of Indian children" (p. 18). The last residential school in Canada closed in 1996.

Most Canadian citizens (settler nonIndigenous) are not aware that in some areas of Canada, almost half of the children who attended residential schools died while in those schools (Mission School Syndrome, 1985). Death of young children at residential school was due to tuberculosis, malnutrition, and other forms of physical, mental, emotional, and spiritual abuse. The residential school of ideology dictated that religion and domestic duties comprised the 'education' deemed important for Native children. In residential schools, the common experience was religious practices, followed by domestic duties. Girls would learn household domestic skills while the boys would learn trades and agricultural skills. Only a portion of each afternoon of a school day was preserved for 'education.' Civilizing and assimilating Native people were the goals of this 'doomed to fail' law and policy.

Protection, civilizing, and assimilating policies in Canada remain a devastating and torturous factor for Indigenous people. Protective and assimilative laws and policies nearly destroyed the cultural knowledge and practices, stories, experiences, and knowledge of the land for First Nations. These laws were harmful, and Indigenous peoples resisted and confronted these injustices. Consequently, throughout the past half century, many Canadian laws have been amended to correct past injustices.

Provincial Involvement

Through the Indian Act in 1876, the federal government of Canada exercised jurisdiction over child welfare for Indigenous peoples in Canada. The way they enforced this was through compulsory education for Indigenous children, as articulated above 'residential schools.' The provinces in Canada became involved in child welfare in 1951 when revisions to Section 88 of the federal *Indian Act* extended provincial laws of general application to Indians and lands belonging to Indians. At that time, provinces were not involved in the 'well-being' or welfare of Native children. The amendment extended provincial child welfare activities and practices to children on reserves. Without Section 88, provincial legislation would not apply to Indians because Canada's constitution gives the federal government the exclusive power to legislate laws and policies regarding Indians. The changes were somewhat controversial, the federal government feeling that any developing provincial laws would be deemed unconstitutional while Indigenous peoples fought against this, feeling that the federal government was reneging on their fiduciary responsibility.

By the 1970s, First Nations peoples across Canada had started to confront and challenge these issues. Although amendments were intended to address Native issues, public policy continued to promote assimilation of First Nations children into the dominant culture. The federal government began to dismantle the residential schools in the 1960s and 1970s and replaced them with 'day schools' (which are still controlled and operated by Indian Act civil servants). As residential schools were 'phased out,' government continued to assimilate Indigenous peoples through practices of child removal, which is remembered by many Indigenous people in Canada as the '60s scoop.' (A term used to describe the highest numbers of adoptions, which took place in the decade of the 1960s. These were so described because, in many cases, children were literally scooped from their homes and communities without the knowledge or consent of families and communities (http://www.originscanada.org/aboriginal-resources/the-stolen-generation/).) This government practice marked a dark period of history for Aboriginal people because the adolescents who returned from residential schools never experienced or received love and affection within these schools. The only parenting they knew for up to 10 years was from the religious order (nuns and priests) and they had been deprived of opportunities to develop positive cultural parenting skills. When these residential school survivors became adults and parents, the government ultimately labeled them as incompetent and unable to raise their own children, and deemed them to be in social need. In many circumstances, this was the government's justification for removing these children and placing them into provincial care. Throughout the 1960s and 1970s, the government continued to apprehend Aboriginal children in the province of British Columbia. According to Patrick Johnston (1983):

> In 1955, there were 3433 children in care of B.C.'s Child welfare branch. Of that number, it is estimated that 29 children, or less than one percent of the total were of Indian ancestry. By 1964, however, 1466 children in care in B.C. were of Indian extraction. That number represented 34.2 percent of all children in care.
>
> p. 23

Today the statistics are even worse. Newly released data from the National Household Survey suggests that "of the approximately 30,000 children in care in Canada in 2011, 14,225 (48 percent) were aboriginal" (Woods and Kirkey, 2013). Clearly these staggering statistics show that almost half of the children in care in Canada are Aboriginal even though Aboriginal people comprise only 3% of the overall Canadian population.

There are many reasons 'defined by government' why Native children are placed into foster care. The most common rationale for the removal of children is neglect, poverty, housing, and substance misuse. These variables are all areas in which the child welfare system takes action for removal, as articulated by

Cindy Blackstock, Executive Director of the First Nations Child and Family Caring Society of Canada:

> "What we have here is a very dire statistic for children who, just like their parents in many cases, are being removed from their families because of state neglect", Blackstock said. "The government is simply not giving these children the same opportunity to grow up with their families that all other Canadian children enjoy."
> Quoted in Woods and Kirkey, 2013: np

For over a century, the government of Canada has maintained and enforced laws, which confined Indigenous people to small parcels of land, defined who is or is not a Native person, and outlawed many ceremonies and Indigenous governance systems, which had been in place. Moreover, Canadian law forced Native people to adapt and live according to European standards. Indigenous peoples became subservient to colonial laws and policies, a term described by Antonio Gramsci (1971) as 'hegemony.' Hegemony is a way of thinking and being, and it occurs when oppressed groups take on dominant group thinking and ideas uncritically. Hegemonic thinking and living is the definitive way to colonize people; the colonized continue the cycle of colonizing themselves (Smith, 2003).

Ultimately, as a result of these laws, Indigenous people throughout the country including those living on their reserves became poverty stricken. Due to this forced assimilation, which marginalized our people further, Native people face racism and stereotyping, which affects our ability to successfully and with confidence to partake in employment, education, and governance.

Interim Measures – A Step in the Right Direction?

Over the last half century, Indigenous leaders have confronted both the provincial and Canadian governments and demanded that child welfare for Indigenous children be centered within Indigenous policy, practices, and worldviews. This includes the necessity for autonomy and authority over the governance of child welfare for Indigenous communities. According to Armitage (1995), "The vision of independent jurisdiction with its own laws is clear, but the process of putting it into place and the form that it will take are not yet defined" (p. 131). In the 18–23 years since the publication of *Liberating our Children, Liberating Our Nations* (Community Panel, 1991) and since Armitage's identification of First Nations' vision for independent jurisdiction, the self-determining vision remains unfulfilled. Currently the Provincial government in British Columbia, the Ministry for Children and Family Development (MCFD) provides authority over voluntary services, guardianship, and child protection through a broad range of child welfare services, including services that protect children from abuse and neglect, services for children with disabilities, adoption services, and family support programs. MCFD delegates these services to Indigenous agencies and communities under the authority of the *Child, Family, and Community Service Act* and the *Adoptions Act*. Through delegation within this governing system, approximately 140 of the 198 First Nation communities in British Columbia have been delegated by the province to provide child welfare for their communities. Communities that choose this type of 'delegated responsibilities' provide unique cultural services that meet the needs of their people. Yet, the overall policies and laws are still under the auspices of the provincial government.

Analysis of This Policy Story

Today, some Indigenous peoples view 'delegated' models of child welfare as a tool of colonialism, based on dominant culture's assumption that the "values of other cultures are abnormal and in need of correction" (Community Panel, 1991: p. 5). Brown et al. (2002) have also identified British Columbia's provincial delegated authority as neocolonial and go on to say:

> Delegated services are founded on the notion of 'giving' authority to deliver child welfare services, rather than recognizing First Nations inherent authority to care for their children. Further, it imposes a way of thinking about and practicing child and family services that is based on mainstream concepts, beliefs, and practices. While delegation allows for some adaptation to accommodate culture and promote community empowerment, it doesn't challenge the fundamental beliefs that construct concepts of child protection. Is delegation wrong? Not entirely. It provides a mechanism for community empowerment …. It is about working inside a box constructed by someone else.
> p. 146

Although the neocolonial landscape of delegated authority currently persists, First Nations people have, in fact, demanded the recognition of the "rights of our people to take responsibility for our own lives" and the "inherent right of our people to govern ourselves" (Community Panel, 1991: p. 29). There is a strong belief among Indigenous people that jurisdiction and legislation over Indigenous child and family services should be returned to them and that legislation must recognize the paramountcy of family and child law enacted by Indigenous Nations.

The Royal Commission on Aboriginal Peoples (RCAP) was a federal government research project where a panel of Indigenous researchers visited many Aboriginal communities between 1991 and 1995. The mandate of the Commission was to study the evolution of the relationship between Aboriginal peoples, the government of Canada and Canadian society as a whole. The Commission heard from many First Nations people who expressed the need for Aboriginal-specific legislation at the federal level in the area of child welfare. RCAP noted:

> In our view, the authority for legislating child welfare and regulating practices should rest with the First Nations people. Native people argued that with Aboriginal jurisdiction in place, there will be greater flexibility to introduce practices in keeping with Aboriginal culture and community realities.
> Royal Commission Report, 1997: p. 376

The Spallumcheen Experience

In 1980, the Spallumcheen people in British Columbia established the first Aboriginal child welfare agency, through

a band-by-law model, (Within the Indian Act, 'Band' is used to identify a First Nations community in Canada. First Nations Bands are given a Band number that identifies their community. In addition to allocating a Band number, each member of the Band receives their own individual status number, identified by the federal government.) which releases them from provincial laws and standards (Royal Commission on Aboriginal Peoples, 1996; Union of BC Indian Chiefs, 2002).

Spallumcheen passed a written bylaw, declaring their own jurisdiction over their children. The Minister of Indian Affairs, who has a veto power over band bylaws under the *Indian Act*, did not veto the bylaw. Spallumcheen people sought out provincial government's approval by organizing a march and demonstration at the then provincial Minister of Human Resources, Grace McCarthy's house, where almost 3000 people including children from the Spallumcheen community and surrounding First Nations people attended. This action pressured the province into recognizing Spallumcheen bylaw. McCarthy signed a handwritten agreement stating Spallumcheen children in British Columbia were recognized through the Spallumcheen bylaw. This bylaw was the first contemporary case of an Aboriginal nation-governing system to reassert its authority and jurisdiction over its children. As of 2009, according to Chief Wayne Christian, Spallumcheen continues to be the only First Nations community in Canada whereby they have their own legislation for the care of their children. In this model, Spallumcheen social workers are authorized by their own community governance to provide child and family services to their membership and to take full protective action when warranted. This is an example of full jurisdictional and legislative authority over child welfare services resting in the hands of Indigenous government.

This governance model for child care allows the Spallumcheen people a greater degree of authority over child and family service matters involving their people. Although this form of community governance has been effective for Spallumcheen people, the federal government stated that they would never sign or approve another governing system as this. Hence, Spallumcheen is the only First Nations community in Canada to implement this bilateral agreement. It should be noted, however, that the Canadian government indicated in 1999 that it would not recognize any other First Nation bylaws guaranteeing sole jurisdiction over Aboriginal Child and Family Services in British Columbia to First Nations (Storey, personal communication, 2002). The Union of BC Indian Chiefs (2002) perceives this as detrimental and states:

> A child welfare bylaw would allow the federal government to recognize Indigenous Peoples' partial re-assumption of jurisdiction for child welfare without requiring new legislation, and would represent an improvement over the current system where Canada requires that Indigenous Peoples seek delegated provincial authority.
>
> p. 38

The Spallumcheen movement led to a number of First Nations communities across Canada looking for more formalized relationships in which they could take over their own child and family services. Green et al. (2012) expand on the Spallumcheen experience with a call to other Indigenous leaders to rewrite policy in the struggle to reduce apprehensions and reclaim Indigenous children: "It is time for our programs, our leaders, to think outside their 'policy box' and outside our circle and to be creative in child welfare development" (p. 110). Clearly, the passing of a Band Bylaw resolution, as was the case for Spallumcheen, led to a return of full jurisdiction and authority over the well-being of their children!

Delegation

The province of British Columbia is similar to other jurisdictions in Canada, in that they may delegate their authority for delivering child welfare services to specific groups in accordance with provincial legislation. In British Columbia, this is done so through the *Child Family and Community Service Act*, (1996) ((CFCSA) or the 'Act'). Social workers are required to receive provincially legislated training for three designated areas in order to provide the necessary services. Caring for First Nations Children Society (an Aboriginal run agency) trains many of the Aboriginal and non-Aboriginal social workers hired by Aboriginal child welfare agencies in British Columbia. The legal authority of the British Columbian government to enter into delegation agreements is expressed in section 90 of the CFCSA.

For the purposes of this act, the Minister may make an agreement with any of the following:

1. an Indian band or a legal entity representing an Aboriginal community;
2. the government of Canada, the government of a province of Canada, or the government of a jurisdiction outside Canada, or an official agency of any of these governments; and
3. any person, or group of persons (1996).

The acceptance of the delegated model by First Nations agencies, communities may be seen as a capacity building step toward self-determination, one which will allow the Aboriginal agency to develop the infrastructure, services, and human resources to provide quality service for Indigenous peoples. A recurring theme in the document *Liberating Our Children: Liberating Our Nations*, was that "the paramountcy of Aboriginal law is necessary to properly recognize the inherent Aboriginal right to the care for Aboriginal children" (Community Panel, 1991: p. 18). The Aboriginal people's council questioned whether the delegation model is a step toward the eventual recognition and affirmation of inherent Aboriginal rights regarding children, or whether it is government's way of absolving its financial responsibilities (p. 3).

In 2002, Ormiston interviewed 16 workers from 4 Indigenous agencies in British Columbia to identify and analyze the effectiveness of the child welfare delegation model currently operating in British Columbia, from an Indigenous perspective. What clearly flowed from the research were the following recommendations:

1. Communities should begin exploring the idea of developing and implementing separate legislation in the area of child and family services.

2. Preventative services in Aboriginal communities should be the priority, with a strong emphasis on culture and traditions.
3. More focus on competency-based hiring criteria for social workers; less emphasis on formal education.
4. Providing education and awareness on a regular basis within the community as part of the agency's mandate.
5. Ongoing awareness/education is essential for ministry staff in terms of how delegation works and the role of Aboriginal agencies.
6. Agencies should be encouraged to negotiate 'blanket' funding arrangements, which will allow them more autonomy in choosing how to allocate their funds.
7. There should be a clear division between child welfare agencies and band councils (Ormiston, 2002).

Current and Future Strategies of Child Welfare Resurgence for Our People

In 2008, MCFD was in the process of transferring legal authority for child and family services to regional community governance structures. They planned to establish parallel Regional *Aboriginal* Authorities by the end of the fiscal year 2008–09. While there was strong support for the future establishment of Regional Aboriginal Authorities, these authorities never came to fruition. The government did not have the political will in the end for this to get passed in the legislature. The British Columbia Assembly of First Nations (BCAFN), along with other Aboriginal policy tables, continued participating in the struggle for jurisdiction over Indigenous children in this province. This was stated in their declaration as:

> That the Ministry of Children and Family Development enter into consultations with regional and provincial planning bodies, duly organized by Aboriginal communities, to begin drafting child welfare legislation specific to Aboriginal children that mandates Aboriginal approaches to child and family development.
>
> BCAFN, 2011: np

Paul Lacerte, Executive Director of the BCAFN expands on the importance of this imperative:

> We are involved in policy discussions with the Ministry on shifting provincial financial resources from paying non Aboriginal people to care for our children, primarily by way of foster homes, towards investments on family supports, family violence and neglect in our communities.
>
> Personal Communication, 2013

Lacerte speaks to the importance of making families resilient and self-determining once again, as opposed to the removal of children, which is what child protection in British Columbia currently does and shifting resources to prevention and early intervention work.

The Indigenous Child Welfare Research Network (ICWRN) was developed through the University of Victoria in 2008. Its vision is to "establish a Research Institute in the province of British Columbia to ensure our children and families are nurtured with stories, traditional teachings and practices relevant to our diverse territories, languages and teachings" (Indigenous Child Well-being Research Network, n.d.: np). This network provides research training to communities throughout British Columbia. Research training here is defined, developed, and implemented from diverse and distinct cultural teachings. In essence, these training sessions teach that 'stories' and 'cultural knowledge' is knowledge that can serve to develop programs, policies, and laws to strengthen children, families, and their communities.

In Conclusion

We will close with our personal Indigenous teachings that inform the importance of cultural knowledge as a foundation for contemporary child welfare practices. Ormiston who is Tlingit, speaks to how Tlingit values inform best practices. Tlingit people are located in the northern part of Canada and Alaska and for Tlingit people they used the 'consensus' process embedded through teachings of the potlatch to honor relations with one another and a method to make important decisions, based on philosophies of respect. When reflecting on traditional teachings and ways of 'living' today within community and in the field of 'social work,' we realize that Tlingit philosophies are critical when developing and implementing new ideas, relations, programs, and the overarching policies that guide these formations. Westerners may critique this 'consensus process' as being time consuming or resource driven, but Indigenous traditional teachings say that it really is the process, the time taken in building relationships and ensuring decisions are made collectively, which is important and reflective of an Indigenous paradigm.

Green who is Haisla, speaks to notions of 'helping' from a Haisla perspective. For Haisla people who are located in the northwest coast of British Columbia, there is a term used 'gywaghlaab,' which means helping one another. The philosophy here is that when a family notices another family faced with challenges or problems, they stop what they are doing to help the family. If there is a community in distress, the Haisla community gathers to help them. A notion of 'helping' was and is a way of life – there were no rules of how to or when to help. People knew when to help. For Tlingit and Haisla teachings and philosophies, cultural knowledge and practice was policy that strengthened and maintained Indigenous peoples for many years. There are important Western systems and Indigenous traditional child-rearing practices that can be used 'together' to develop and implement appropriate services for Indigenous children, families, and communities. It is essential for all social workers to understand the history of how Canadian laws and policies have confined Indigenous people. In doing so, we must collaborate on ethical and cultural practices to ensure that Indigenous knowledge; ceremony and culture are central to enhancing the well-being of children and their communities.

Abstract

This article aims to give both an overview as well as to develop certain critical thinking tools that can help a reader engage with the complexity and diversity of Indigenous knowledge and intellectual property rights. It considers the cultural specificity of intellectual property law as well as looking at sites of contemporary struggle. Embedded in the article are questions of knowledge and power as well as how historical legacies of colonialism continue to affect the way we interpret the world and its cultures. The article also raises questions about legal authority and the way frameworks for participation and interpretation in legal contexts are produced and made available to parties that have been marginalized from such spaces.

> Research within late-modern and late-colonial conditions continues relentlessly and brings with it a new wave of exploration, discovery, exploitation and appropriation. Researchers enter with good will in their front pockets and patents in their back pockets, they bring medicine into villages and extract blood for genetic analysis. No matter how appalling their behaviors, how insensitive and offensive their personal actions may be, their acts and intentions are always justified as being for the 'good of mankind'.
>
> Smith, 1999: p. 24

> Indigenous peoples have the right to maintain, control, protect, and develop their cultural heritage, traditional knowledge, and traditional cultural expressions, as well as the manifestations of their sciences, technologies, and cultures, including human and genetic resources, seeds, medicines, knowledge of the properties of fauna and flora, oral traditions, literatures, designs, sports and traditional games, and visual and performing arts. They also have the right to maintain, control, protect, and develop their intellectual property over such cultural heritage, traditional knowledge, and traditional cultural expressions.

> Article 31, *United Nations Declaration on the Rights of Indigenous Peoples*, September 2007

Introduction

The intersection of Indigenous knowledge with intellectual property law has produced one of the more complicated legal problems in the contemporary present. This is partly because the issues regarding the protection of Indigenous knowledge are not only legal in nature but also raise questions of historical injustice and colonialism, and at their core reveal that intellectual property law is a culturally specific body of law that was designed for a very specific purpose. Despite its claims to universality, there exist knowledge systems that intellectual property law was never designed to incorporate or protect.

Another complicating factor is that discussions about this issue are not only located within the legal discipline, but are spread across the sciences and humanities. This means that multiple discourses, with very different objects of inquiry, produce different and sometimes contradictory interpretations. Moreover, the problems that intellectual property law raises for non-Western knowledge systems are directly experienced in communities across the globe. Unfortunately these experiences are not always included in the disciplinary analyses that tend to focus more on abstract elements like definitions, boundaries of knowledge systems, and legal rationalities. This results in multiple registers of meaning – those produced through experience and those constructed through disciplinary foci. This leads to different interests and interpretations of what makes this problem to start with, and importantly, what options for adequately dealing with it are available.

Indigenous representatives in multiple countries and contexts including (but not only) Australia, the United States, Indonesia, Brazil, the Philippines, India, Canada, Vanuatu, Cook Islands, Kenya, Peru, Namibia, Mexico, Jordan, Russia, and Sweden argue that they have legitimate rights to control, access, and utilize in any way, including restricting other's access to, knowledge or information that derives from unique cultural histories, expressions, practices, and contexts. A key concern in the intersection of Indigenous knowledge with intellectual property law has also been the inevitable translation of Indigenous knowledge systems into frameworks of western property, complete with principles of alienation, exclusion, and exclusive possession. Such property systems are often not culturally compatible, as the translation into western paradigms requires foundational transformations in how knowledge is understood and how it is shared. Such transformation often sheers off the complexity, interconnection, and intelligibility of these knowledge systems in order to render them legible for property-style protection. This translation and transformation raises very real concerns from Indigenous peoples.

One of the most significant challenges for the protection of Indigenous knowledge systems is that intellectual property has a unique European derivation, and this informs its modes of classification, identification, and operation (Rose, 1993; Drahos, 1996; Sherman and Bently, 1999; Deazley, 2004). Intellectual property law promotes cultural interpretations of knowledge, ownership, authorship, and property. For intellectual property law, the individual as author, genius, owner, and creator hold a central position. These frameworks do not necessarily correspond or compliment Indigenous people's understandings about the role and function of knowledge, or the role of individuals within communities and the joint responsibilities for collectively developed and held knowledge. As intellectual property law has developed from a Eurocentric location and logic, alternative conceptualizations have been very difficult for this area of law to acknowledge and absorb.

There is no easy compatibility between intellectual property law and Indigenous knowledge systems. Their intersection raises issues that involve both legal and nonlegal components, are almost always political, sometimes controversial and can produce conflict in ideals, values, and desired outcomes. Problems, concerns, and claims are not always commercial in nature, and can involve ethical, cultural, historical, religious/spiritual, and moral dimensions. For example, inappropriate use of sacred cultural artifacts, symbols, or designs may not cause financial loss but can cause considerable offence to the relevant community responsible for the use and circulation of that artifact, symbol, or design.

With a field this large and spread across so many different community and disciplinary locations, it is not possible to give voice to every instance, concern, or interpretation. In this regard the article has specific limits. This article is arranged without presuming prior knowledge of Indigenous rights or intellectual property law. By necessity it is also deeply interdisciplinary.

The discussion begins with the one central theme that underpins this issue at very basic and functional levels. This is the role of colonialism, law, and the treatment and construction of Indigenous peoples. The issue of intellectual property and Indigenous knowledge only arises because of this history. Therefore it must be understood in relation to these dynamics especially as they continue to fold into the issues themselves. To not address these is to perpetuate a profound silence of dispossession, presumed superiority, and discrimination: a past that nonindigenous peoples have largely benefited from and that still has significant effects today. This article then moves to address definitions and classificatory frameworks as well as considering the way in which intellectual property law has been made and remade over time. This is important for appreciating the way in which intellectual property law is not ahistorical and timeless, but is constantly evolving as new concerns and problems arise. What makes intellectual property law so powerful and important in our present society is precisely the way it has been able to adapt and develop in reach and scope, and to incorporate new technological and other developments.

The three specific sites to be explored where intellectual property and Indigenous knowledge issues play themselves out include: in art, in archives and museums, and in relation to biodiversity. All are illustrative of the tensions and challenges faced by Indigenous peoples and the very real difficulties for developing new forms of legal and social responsibility and respect for cultural differences in the use and circulation of Indigenous knowledge and knowledge products. This article will then detail some of the developments at an international level raising questions about how, in the international context, the debate itself is constructed and with what kind of participation and by whom. The final section of this article will focus on several recent developments that are designed to enhance Indigenous positions and strategies in both legal and educative ways.

Colonialism, Law, and Indigenous Peoples

Concerns for the protection of Indigenous knowledge have increased in visibility, circulation, and recognition in the last 30 years. Over this period, expectations and strategies for explaining and phrasing concerns have shifted and changed. At the core however, remain the structural, classificatory, and discriminatory legacies of colonialism. These have contributed to the ways in which Indigenous peoples were viewed and treated, and consequently how their knowledge systems have been treated. To be clear, because Indigenous peoples have historically been constructed as 'primitives,' 'savages,' and less than human; as homogenous groups of people despite different languages, customs, practices, and cultures; and as objects of curiosity for study, collection, and research, Indigenous knowledge systems have been treated in the same way. It is this lack of respect and dignity for Indigenous peoples as peoples and as part of sophisticated cultures with inherent rights to their cultures and their lands that make this problem in the first place. Importantly, the failure to account and accept difference on its own terms rather than through the narrow Christian and European lenses offered, continue to play out in many ways. Two of these include how Indigenous concerns in the present can be recognized, heard, and treated as legitimate; and how the same legal systems that facilitated Indigenous dispossession can be rehabilitated to include Indigenous interests.

Colonialism is one of those words that can cause unease. It is also something that many assume they already know enough about – it refers to a period in the past that is increasingly further and further away. Yet colonialism continues to condition the present in multiple ways. It is what makes modernity possible and it continues to function and underpin our modern social order (Quijano, 1999; Mignolo, 1995, 2000, 2011; Moraña, Dussel, and Jáuregui, 2008). Colonialism has many components and many different histories, trajectories, and effects. It is full of conflict and contradiction.

Central to the function and instrumentality of colonialism is law, as it is law that establishes the frameworks and the conditions for colonial conquest, domination, and control. The development of colonial legal systems foundationally affected the ways in which Indigenous peoples, as colonial subjects/objects as well as their laws, customs, and systems of governance, were recognized and treated within the colonial order of things. As Sally Merry explains:

> Colonialism typically involved the large-scale transfer of laws and legal institutions from one society to another, each of which had its own distinct socio-cultural organization and legal culture. The result was a dual legal system: one for the colonized peoples and one for the colonizers … [t]he language of transfer and duality, however, ignores the central feature of colonialism: It was a process in which one society endeavored to rule and to transform another … [t]hus, law, along with other institutions of the colonial state, transformed conceptions of time, space, property, work, marriage, and the state. The role law played in the colonizing process is an instance of its capacity to reshape culture and consciousness.
>
> Merry, 1991: p. 891

Colonial legalities in new territories sought to render already existing laws, customs, and forms of governance as inferior to these newly transferred laws and institutions. Intrinsically they sought to change and reshape social expectations and behavior.

With imposed legal systems underpinned by new Christian moral value systems, those peoples subjected to these new frameworks were also positioned within hierarchical networks of relations that placed the colonists at the top and those 'other' peoples underneath. This 'positional superiority' naturalized discriminatory practices and embedded entitlement to conduct and govern according to a Eurocentric logic (Said, 1979). As colonialism advanced across and into new territories, so too did new governing techniques and new Enlightenment forms of classification and categorization, all of which targeted colonized peoples.

Alongside control of lands, control of knowledge became central to achieving colonial governing ambitions. This rendered many colonized peoples open to invasive and destructive regulatory and research practices. As Linda Tuhiwai Smith observes:

> Indigenous peoples were classified alongside the flora and fauna; hierarchical typologies of humanity and systems of representation were fuelled by new discoveries; and cultural maps were charted and territories claimed and contested by the major European powers. Hence some Indigenous peoples were ranked above others in terms of such things as the belief that they were 'nearly human', 'almost human' or 'sub-human'. This often depended upon whether it was thought that the peoples concerned possessed a 'soul' and could therefore be offered salvation and whether or not they were educatable and could be offered schooling. These systems for organizing classifying and storing new knowledge and for theorizing the meaning of such discoveries constituted research. In a colonial context however, this research was undeniably also about power and domination. The instruments or technologies of research were also instruments for legitimizing certain colonial practices.
>
> Smith, 1999: p. 60

The legacies of colonialism are apparent in how legal frameworks sought to position colonized and Indigenous peoples and their concerns (Benton, 2001; Keal, 2005). Colonial law sought to manage how these 'subjects' were recognized and translated in a myriad of contexts. While there was no 'grand plan' or homogenous colonialism, the 1452 Papal 'Doctrine of Discovery' certainly presented a consistent template for engaging with Indigenous peoples. It expressly gave Christian explorers the right to claim discovered lands that were not inhabited by Christians. In the attempts to recognize and deal with the peoples already existing on lands subject to colonial ambitions there were notable differences across jurisdictions, for example in Northern America, initially Indigenous peoples were treated as distinct entities and formal legal relationships (treaties), based on the prevailing international law, were entered into. This was later replaced by more oppressive ideological doctrines like Manifest Destiny, which subverted Indigenous rights and further justified the taking of lands and territories across the Americas. In other contexts like Australia, which was colonized under the doctrine of *terra nullius* (meaning 'no man's land'), the mere presence of Indigenous peoples was harder to deal with because the doctrine posited that they actually were not there. This resulted in classifications of Aboriginal people as subhuman, and later, childlike, which had obvious consequences in terms of how Aboriginal people were placed under extreme regulation and governmental control well into the 1970s.

The reason behind why all this matters for the present discussion is intellectual property law folds into itself prevailing colonial logics about the value of Indigenous peoples and their knowledges. The development of intellectual property did not happen in some kind of political, social, and cultural vacuum, but was slowly assembled during the same colonial periods and was therefore affected by prevailing rationalities and assumptions about non-European peoples.

Definitions and Terminology

Almost all the terms in the debates on the protection of Indigenous knowledge are contested, have problematic histories, and/or defy simple definition. Indigenous, knowledge, local, community, tradition, cultural heritage, public, culture, property, are a sample of the most prominent of these. As Oguamanam perceptively explains:

> It is the norm that the majority of writings on this complex subject devote substantial effort to the clarification of terms. Without doubt, clarification of key terms is congruous to analytical integrity and guards against misleading assumptions. In some contexts, however it may portend some form of red herring or escapist expedition from the substantive questions, especially if every given phrase or term is a contested one.
>
> Oguamanam, 2009: p. 35

The confusion in definitions and terminology moves in multiple directions and has diverse politics. The starting point for many of the definitional concerns is around 'Indigenous peoples.' For example, contests over who is or who is not Indigenous (which implicitly affects the identification of Indigenous or traditional/local knowledge) derives from both early Enlightenment thinking that sought to classify the stages of humanity and in colonial intervention and governance that subsequently created the means for the identification of peoples as Indigenous, Aboriginal, Indian, and so forth. As many Indigenous scholars have noted, these were not terms that Indigenous/Aboriginal/First Nations/Native American people used for themselves, but were created and became imposed forms of legal and social identification that erased the particularity of specific cultural and community names and their significance to identity making. The modern concept of indigeneity is produced through colonial relations (Popova-Gosart, 2012). The emergence of this concept, as an attempt to identify and classify a new category of peoples also, subsequently, informed the first legal and international documents addressing Indigenous rights. (The first international document addressing Indigenous rights and the responsibilities of States toward these peoples was the 1957 International Labor Organization's Convention 107).

The modern appropriation and current mobilization of national and international Indigenous polities draws from this past but has also been graphically subverted and extended in multiple ways, especially through realignments of citizenship and identity. The 2007 *Declaration on the Rights of Indigenous Peoples* is significant precisely because it recognizes the distinctive nature of Indigenous needs in relation to language, education, culture, health, housing, governance, and representation. As James Anaya explains Indigenous peoples, in a legal context, are now defined as "the living descendants of

pre-invasion inhabitants of lands now dominated by others" (Anaya, 1996: p. 3).

The problem of defining Indigenous peoples inevitably extends into Indigenous knowledge. The search for definitions is embedded in a classificatory logic that seeks clarity in the boundaries. Unfortunately such clear boundaries are impossible. This makes many parties very uneasy. While it might not always be clear what exactly Indigenous knowledge is, there must be a strong resistance to the binary of 'Indigenous' versus 'scientific' knowledge, because it upholds very specific power relations (Agrawal, 2002; Anderson, 2009). Knowledge, whether Indigenous, scientific or other, is notoriously difficult to define and identify and as Indigenous knowledge does not really offer itself as a special case to this problem, we need to be wary of situating certain knowledges as oppositional and easier to demarcate boundaries to than others, as this can reinforce cultural prejudices and colonial biases.

Intellectual Property and '*Gnaritas Nullius*'

Intellectual property is a term that often generates confusion. The potential for literal interpretation and the capacity for everybody who thinks to have some kind of intellectual property of their own only increase the problem. Intellectual property is actually an umbrella term used to cover specific laws that are loosely united in their efforts to manage the relationships between an idea and the tangible expression of that idea (a book, a photograph, an artwork, a sound-recording, a design on fabric, an invention). There is no specific intellectual property law named as such. Rather, the independent legislation for copyright, patents, designs, trademarks, trade secrets, confidential information together constitute the 'laws of intellectual property.' They are grouped under this term 'intellectual property' because they are seen to share some dimension of the problematic of determining legally recognized and justifiable rights in the expression of ideas and treating this expression as some kind of 'property.'

Copyright, patents, designs, etc., are specific laws that evolved slowly and haphazardly in Europe from the late seventeenth century. This slow evolution was in response to cultural, political, social, and economic shifts that occurred throughout this period. Some scholars point to the development of the printing press by Johannes Gutenburg in 1450, increasing the possibility of the circulation of texts, as marking the moment where new laws governing the production and circulation of texts began (Eisenstein, 1980). Others point to the increasing development of nation-states following the Treaty of Westphalia in 1648 that saw the increased need for agreements and the development of reciprocal trading rights within and across newly emerging countries leading to the distinct patent and copyright statutes in Britain in 1623 and 1710, respectively. (Statute of Monopolies, 1623 and Statute of Anne, 1720. For some of the work on these see Deazley and also the Web site). Still others point to the emergence and maturity of concepts of property, like those espoused by John Locke, that helped establish the crucial relationships between property and individuals that continues to underpin current intellectual property law (Rose, 1993). Whatever the focus, it is clear that intellectual property law developed because of a combination of all these elements and was a result of significant political and economic changes occurring in Europe.

The early developments do not feature the terminology 'intellectual property.' Nevertheless the early cases make clear that the challenges in determining this kind of property arise from its intangibility: that it constitutes a product of the mind and therefore cannot be easily demarcated and identified in the same ways as tangible forms of property like land and livestock. For new ideas of property to be developed, law needed to create new categories for identifying the characteristics of this new kind of property. This was because of problems about what exactly the property was, how it could be identified, how it could be measured, how loss could be recognized and compensated, what labor the individual exerted to 'make' a work, and generally how a right to something that was intangible could be justified (Anderson, 2009).

For copyright law, the two most important categories developed were authorship and originality. The making of the category of the author within copyright law, and by implication within society, begins most clearly with the literary property cases in Great Britain in the seventeenth century. Yet it was ostensibly relations between booksellers and publishers that pushed the law to consider the category of the author. What this means is that intellectual property law, in various ways, has been influential in shaping some of the most foundational categories that we use in our society. The author as an individual, a genius and someone that exerts certain property rights over cultural products like writing is completely naturalized: to the extent that it is hard to imagine another configuration. But this norm is produced at the expense of appreciating that not all other cultures make this connection, do not have the same ideas about property nor have these concepts permeate their societies in the same way as they have come to dominate Western contexts. This begins to point to some of the incommensurable concepts that arise in the intersection of intellectual property and Indigenous knowledge – that is, Indigenous knowledge is not easily individualized nor easily abstracted, but derives from and maintains meaning in the contexts in which it was developed and redeveloped. Moreover, there is often not a single identifiable author, rather a community of knowledge holders that act as custodians and keepers of the knowledge but not necessarily owners.

In 2010, Indigenous scholar Greg Younging wrote a paper titled *Gnaritas Nullius (No One's Knowledge): The Public Domain and the Colonization of Indigenous Knowledge* (Younging, 2010). In this paper, Younging explains the complex and varied knowledge systems and knowledge products that Indigenous peoples across the Americas have produced for over 500 years from architecture to irrigation systems, from pharmacology to arts and intricate governance systems. Yet despite these significant innovations, the paradigms that newly arrived colonial peoples viewed Indigenous peoples, their cultures, and inevitably their knowledge systems and products, were so impoverished that they were unable to see Indigenous peoples' civilizations as profound and advanced. Like the land Indigenous peoples were living upon which was, because of the discriminatory and myopic colonial legal doctrines, made into the possession and property of the colonists, so too Indigenous knowledge systems were rendered into either curiosities to be collected and gazed upon or taken and appropriated to be

repositioned as someone else's idea and property. If the land upon which Indigenous peoples had lived for hundreds of years could be constructed into the fiction of *terra nullius* – no one's land, so too was Indigenous knowledge and innovation constructed into the fiction of *gnaritas nullius* – no one's knowledge. And as no one's knowledge it was never offered any kind of respect and certainly no legal protection. Intellectual property law, concerned with offering all kinds of different and varied protections never considered Indigenous knowledge valuable. It actively supported the contexts and nonindigenous individuals that appropriated, stole, and/or made this knowledge into colonial and recognizable forms of (intellectual) property.

Sites of Struggle

So how did this actually occur, what was the role of intellectual property in facilitating the dispossession of Indigenous knowledges, and what can this history tell us about present claims and problems? What follows is also an illustration of the inherent cultural biases built into the law in three different contexts. The way law presents itself as political, ahistorical, and acultural is herein undone. The next three examples show more clearly how intellectual property law has served one cultural vision of the world at the expense of others.

Copyright and Aboriginal Art

Art, in its broadest sense, is one area where intellectual property law effectively functions. From literary texts to painting, music, photography, and the performing arts, all now utilize elements of copyright to protect such works. As mentioned above the key relationship that functions at the core of copyright is that the author is the originator and owner of the work, and as the owner, the author has a range of rights that can be asserted over the work; including distribution, copying, licensing, and publishing.

From the moment nonindigenous people first encountered the cultural practices of Indigenous peoples, they were not considered art proper, but more cultural curiosities. Some products of Indigenous cultural practice, like beadwork and weaving in the Americas became highly sought after, but they were never considered 'art' in the sense that deserved protection. From a colonial perspective there were no clear authors and the works were religious, ceremonial, and functional within Indigenous societies. Such works circulated within an alternative regime of value that was unfamiliar to nonindigenous peoples. Instead, Indigenous cultural products were collected and placed in ethnographic museums and adorned curiosity shops. In other instances they became trophies from frontier battles or were used as items to trade with colonists.

In Australia, Aboriginal art is currently estimated to be worth several million dollars within the Australian economy. The making of this art industry is complex and depends not only on interactions between individual and governmental initiatives (Myers, 2000), but also involves the recognition of Aboriginal art as 'art' and therefore open to the same copyright protections as other works. Like in other contexts, prior to this transformation, Indigenous artistry was constructed by anthropological and ethnographic lenses as 'objects' of culture and constituted as 'nonart' captured through the term 'folkore.' As unprotected and valued for its strangeness, Aboriginal cultural products were collected and displayed in private collections and museums, while the persons responsible for making and painting the Aboriginal works were rarely documented. In the 1920s emerging new Australian artists were encouraged to copy the designs, styles, and colors – everything about the works was open to being copied, reproduced, and reused – without concern whether these uses were sensitive or culturally appropriate. The works were considered 'raw material' for other artists to benefit directly from.

In the 1970s there started to be a visible and voiced concern from Aboriginal spokespeople about the large-scale copying of Aboriginal designs and works onto fabrics, tea towels, and carpets. For the Aboriginal producers (not yet recognized as artists), these copies were not only offensive because they failed to acknowledge the original painters and designers, but they also disrupted important cultural stories and narratives that were embedded in the works. As a result, the 1980s and 1990s saw the Australian courts grapple with a series of cases that focused on inclusion of Aboriginal art as a legitimate copyright work. These cases have been repetitively written about in numerous national and international contexts, partly because of their novelty and partly because they really function as the foundational case law in the entire area of intellectual property and Indigenous knowledge. They showed that peoples whose knowledge was historically considered inferior, timeless and without 'authors' could assert legal title to the works and could be recognized as 'artists' in their own right. Due to the strategic work of several key individuals working on these cases, Aboriginal art was included within the intellectual property paradigm and Aboriginal producers were recognized as individual artists who had legally defensible rights in relation to their works.

Through these cases, intellectual property law was shown to be capable and responsive to the inclusion of new subject matter. This deflected attention away from the conditions that led to the exclusions to start with – namely culturally specific categories (of authorship and ownership for example) that privileged some forms of cultural production and not only ignored others, but also endorsed the wholesale copying for nonindigenous artists' benefit. This cultural specificity and hence bias was really only addressed in the margins of the cases, but the law was unable to expand its own presumed neutral categories to include other cultural interpretations of artistry, and importantly, where that artistry came from if it did not come from the individual 'genius.' The complexity of Aboriginal artistry was flattened into the already existing copyright categories in order to secure protection. For instance, copyright law could not cope with the reality that Aboriginal rights to paint certain images came from rights to land, and that Aboriginal artists painted according to complex governance systems and obligations within their cultural contexts, and were not considered exclusive 'owners,' nor were the works considered 'property.' Fitting an entirely different paradigm of cultural production into the narrow terms of Western intellectual property law has come with costs for Aboriginal artists, and while many artists work around some of these confines, the bias within the law still

perpetuates forms of exclusion while at the same time presenting apparent inclusion.

Archives, Museums, Libraries, and Indigenous Collections

While copyright and Aboriginal art prompted some of the first case law in this field, it is also an example of the specific national contours of the emergence of Indigenous knowledge issues more generally. The actions and reactions in Australia were unique and have opened up a significant area of discussion about Indigenous knowledge rights in a range of contexts. Addressing Indigenous intellectual property rights is now integral to governmental funding initiatives and research collaborations which engage with Indigenous people and their perspectives, authority and governance frameworks.

At least since the 1970s, another area of contest and struggle over intellectual property and Indigenous knowledge has been within archives, libraries, and museums. These contests are international because across contexts the issues tend to be remarkably similar. Cultural institutions that hold Indigenous collections are at the forefront of Indigenous peoples' efforts to achieve access and control of materials relating to their families and communities. These issues are understandably acute in settler colonial contexts, where relations with Indigenous peoples continue to be difficult and historical legacies of discriminatory treatment remain remarkably present.

The struggle for control over Indigenous collections within cultural institutions exists because these sites are primary repositories for enormous amounts of materials collected over the colonial period on the lives, cultures, and languages of Indigenous peoples. This was almost always without the consent of those being recorded, and certainly without any clear explanations of where this material would be kept, who would be able to access it, and that it would often be used to prove the inferiority of Indigenous peoples and their practices. Alongside the troubling history of how these collections were acquired and their uses, one main point of concern is that these collections are also not legally owned by Indigenous peoples but rather, by the person, usually a researcher, governmental official or curiosity seeker, who came to the community and made the documentation – either in sound, in film, through photographs, or even written transcription.

In this context, intellectual property law again finds itself on the side of maintaining unequal relationships. For the nonindigenous peoples, rights to this material, regardless of how the material was collected, are upheld. Moreover, through specific exceptions and limitations within the copyright legislation, cultural institutions are given specific options for making the material accessible, especially material that is no longer protected and now exists in the 'public domain.' This is despite Indigenous claims that some of this public domain material should not be circulated, does not have a time period for circulation, and is to be governed according to complex Indigenous authority and management systems. Again copyright is beholden to its own cultural contingencies. In dismissing any role in the social conditions that led to these collections, copyright law nevertheless endorses those very conditions by vesting the ownership and the property rights with those people who 'made' the works. This legal entitlement granted to the nonindigenous recorders assumes that it is they that have the creativity, the genius, and authorship. Those peoples in the recordings and documents remain passive subjects whose representations remain controlled by others. It is this unequal terrain that makes Indigenous peoples so concerned about the collections within cultural institutions. That the law cannot be retroactively undone also means these legacies – with copyright protection extending far into the future (death of the author plus 70 years in almost all jurisdictions that hold this material) – remain very present and very difficult to negotiate (Anderson, 2012).

Biodiversity and Biopiracy

While the ongoing problems over Indigenous collections are probably one of the most substantial areas of concern given the sheer amount of Indigenous materials within collections, they are not very visible in the literature. The area that is the most discussed, and fiercely debated, is over rights to biodiversity and threats of biopiracy – where concerns oscillate around circumstances where Indigenous knowledge about plants, animals, and medicines, is taken and converted into a 'scientific' language of synthesized distinct properties that can be isolated and patented.

This area appears much more complicated than the copyright issues partly because of the different area of intellectual property law that is involved. Patents themselves are difficult because of the extent of the rights, what exactly it is that is protected and the necessary steps to secure protection. Patenting requires access to sophisticated scientific equipment, access to technical language, and access to extensive financial resources to file the patents and to protect them. In this sense alone there are very specific protections for very specialized research endeavors.

Patents over bioresources have been controversial in many other contexts besides Indigenous ones. The first patents over live organisms and, subsequently, cell lines have produced significant commentary ranging from justification to ethical questions to future implications. The opportunities to patent live organisms and biocompounds have corresponded with significant technological developments in the biotechnology arena, and this has led many researchers to remote and bioresource-rich contexts: contexts often inhabited by Indigenous peoples.

There are multiple examples of patents that have provoked significant condemnation because they are based upon already existing Indigenous or traditional knowledge and therefore should not meet the standard of 'novelty' for the patent grant. The most discussed patents in this context are turmeric, neem, and ayahuasca – and significant efforts have been made to have these patents revoked. Anthropologists like Cori Hayden and Shane Green have provided much needed analysis in tracing the ways in which researchers come to gather botanical samples from Indigenous communities, and the challenges in translation and understanding about what is exactly going on and for whose benefit (Hayden, 2003; Greene, 2004).

One of the most infamous cases of bioprospecting and patenting involve the San people of South Africa, Namibia, and Botswana and the Hoodia plant known for its appetite suppressant properties. A case that has produced a significant amount of literature, it raises issues about the early documentation of Indigenous medicinal knowledge in the colonial

period, how knowledge about these properties was transmitted to researchers who began developing new drugs based on this knowledge, how this activity happening in labs and involving significant financial interests and pharmaceutical companies, was made known to the San and the subsequent negotiations over consent and benefit sharing (Wynburg et al., 2009).

The problem for intellectual property is, again, the conditions embedded in the grant of the property right that privilege certain actors over others. Those that benefit are those that have access to the language, technology, and financial resources. Indigenous peoples are seldom in these positions, and their knowledge is regarded as 'raw material' from which others can extend and benefit from. In this paradigm, there is very limited space to recognize the long and substantial work Indigenous peoples have made to refining this knowledge, nor acknowledgement of the labor that is involved in determining which plants have special properties and which do not. For those seeking to utilize Indigenous environmental knowledge, it is almost assumed that Indigenous peoples developed knowledge about the properties of plants by chance, rather than through innovation, invention, and hard work. This treatment of Indigenous knowledge is completely consistent with the embedded colonial assumptions about Indigenous peoples as backwards and limited. Thus the patent system reinforces this view of Indigenous peoples and their knowledge by not according them legitimate status or authority in the discovery and husbandry of these plants and their medicinal and health-based properties.

International Interest and the World Intellectual Property Organization

Key agencies like the World Intellectual Property Organization (WIPO) have been instrumental in establishing new frameworks for the interpretation of Indigenous interests in intellectual property. This includes setting new parameters for identifying Indigenous knowledge in need of protection. For example, the three discrete areas to refine discussion and policy development are now conceived as: 'genetic resources,' 'traditional knowledge,' and 'traditional cultural expressions/folklore.' In international contexts, these new phrases do more than ameliorate contest. They streamline the discussion in important ways so that the international framework assumes an authoritative position and starts to function as the point of departure for any discussion of the issue. This has the additional effect of enhancing the reputation and authority of the body that is circulating them to start with.

The WIPO has come to hold a central position in relation to debates around intellectual property and Indigenous interests therein. This was not always the case. There is sufficient evidence to suggest that countries like Australia, India, and Canada would have had the debates about intellectual property and Indigenous knowledge regardless of international attention and reworked interagency agendas. (This is because the claims in these countries arise out of the particular colonial politics arising from land rights. Australia's interest predates the WIPO focus by at least 20 years).

Even though discussions about the protection of Indigenous knowledge (specifically biological knowledge) have also been channeled through the Convention on Biological Diversity (CBD) and UNESCO retains expertise in relation to cultural property or tangible and intangible cultural property, WIPO remains the key site for making meaning about the legal possibilities for the protection of Indigenous knowledge through intellectual property law. This speaks to the modern significance and importance of intellectual property law itself. The politics of intellectual property law, and the diverse range of contexts that it reaches into, affects any contemporary discussions about knowledge protection. Importantly, and because of this, it also mobilizes a range of interested parties that might otherwise have no reason to pay attention to Indigenous knowledge issues.

Future Options and Strategies

Despite the historical use of intellectual property law against Indigenous peoples and their knowledge systems, Indigenous peoples also see potential opportunities within this body of law. This forward-looking approach recognizes the power of intellectual property law. But intellectual property law is not a panacea. It still remains firmly grounded in Eurocentric visions of the world, which include ideas of property, the concept of individual creation and genius that happens in a context void of human relationships, and that it exists to foster economic return. In circumstances where Indigenous expectations are malleable and can meet these embedded assumptions, intellectual property law can work quite effectively. When the needs differ, for instance in asserting community rather than individual authorship, or when there should be no time period for protection, intellectual property law is not necessarily the best option.

The problem for Indigenous peoples is that they are experiencing a range of problems in multiple areas of knowledge control and knowledge governance, especially when dealing with nonindigenous people and other third party interests. It is unlikely that one specific legislative development could comprehensively solve all the issues currently being encountered. While the development of an international approach to Indigenous intellectual property issues is important, there is also an urgent need to develop local strategies that are appropriate to both community and context and are more immediately accessible.

The extent of current proposals reflects the complexity of the issues for law, policy, and local/national/regional/international governance. Due to space constraints these cannot all be outlined here but can be found elsewhere (Anderson, 2010). While they are neither uniformly coherent nor necessarily applicable for every instance or in every context, they can be loosely grouped into six separate categories:

- Proposals that modify the current intellectual property framework;
- Proposals that utilize other areas of critical intellectual property discourse;
- Proposals that target private law solutions;
- Combined approaches;
- Alternative regimes; and
- International treaties and conventions.

That the proposals range from international and overarching frameworks (treaties), to localized and targeted strategies (private law making), reflect the different opinions about

what the nature of the problem is and what kinds of solutions might be developed that would provide immediate relief or remedy. Given the complicated dimensions informing this area, a singular solution is perhaps inappropriate. Importantly, any successful intervention in this area is dependent upon the capacity for Indigenous people and communities to make informed decisions about what options are available and appropriate for each problem and each context.

Research Agreements and Protocols

In order to deal directly with the problem of researchers within Indigenous communities and the embedded assumption that the researcher comes, does his/her research and then leaves with all the material gathered, research agreements and protocols have been developed. Protocols have played an important role in establishing new kinds of relationships between Indigenous people, Indigenous communities, and other organizations and/or nonindigenous people.

In general protocols can be understood as context-driven policy. They can be developed to address specific problems and provide guidance in relation to appropriate behavior when it is required. Protocols can incorporate community perspectives, and targeted to particular issues. For example, protocols have been developed for libraries and archives, for visual artists, for collaboration between filmmakers and increasingly for relationships around access to environmental knowledge.

A protocol is a code of conduct, a guideline, or a set of manners that explains how people should behave in certain circumstances. Protocols make new kinds of negotiation possible. They can be used to set community standards around knowledge circulation and use for outsiders as well as help change attitudes and set new standards. Generally, protocols are flexible and can change over time. It is important to see them as a tool to help achieve certain goals that other areas of law have been unable to fulfill. As formal or informal guidelines for behavior, protocols can help build relationships and make new ones possible.

Protocols are prescriptive and they offer Indigenous people a range of options. This is especially in situations when Indigenous people may not want to engage with formal law mechanisms, but rather find means for articulating customary law, or local laws specific to the context. Protocols provide conditions for Indigenous agency in the sense that they can embolden already existing practices rather than imposing new ones. This is one of the central reasons why they have been adopted and are increasingly found across all areas involving negotiations around Indigenous knowledge use.

International Legal Instruments

For the last 12 years, the WIPO has been working on developing an international legal instrument or instruments in this area. Currently there are three instruments being negotiated: one for 'genetic resources,' one for 'traditional knowledge,' and one for 'traditional cultural expressions.' The proposals for international instruments in this area provide an opportunity to streamline activity, ask fundamental questions about what is at stake and for whom, and develop an appropriate approach. Importantly they could offer an overarching authoritative framework for negotiating equitable relationships in the use of Indigenous knowledge.

Yet questions of jurisdiction, enforceability, and constructing foundational concepts remain as significant challenges. The highly contested political nature of Indigenous knowledge debates also slow the progress of development. Other questions about consensus, Indigenous participation in design, voting, and whom the instruments would be between again engage historical legacies that are not easy to resolve. Sensitivity to the range of complex interests, as well as the unequal negotiating positions that Indigenous people occupy in practice will directly affect the success and the usefulness of any new instrument/s.

Within the UN CBD, there has been sustained effort to develop mechanisms that recognize the value and significance of Indigenous knowledge within the life sciences and biotechnology industries. In particular, the CBD has been working to develop an international regime on access and benefit sharing of biological resources. This scheme seeks to develop equitable means for Indigenous communities to derive benefits from any knowledge that they grant access to in the context of genetic resources. Such benefits for the Indigenous community are not necessarily dependent upon the future financial benefits that may be developed. Rather, the scheme aims to create conditions where the knowledge of the source community is recognized and valued at the point of transfer/exchange. Access and benefit sharing is dependent upon the making of agreements between parties that recognize the contribution that each makes as well as the value of that contribution.

The development of an access and benefit-sharing scheme recognizes the value of Indigenous people's knowledge, especially in areas where it has become highly desired. Not only do Indigenous people have the right to be involved in any decision making within research projects that involve themselves or their knowledge, but they also have the right to derive benefits from any products that are developed as a result of these participatory projects. However, the use of contract law, while offering a legal framework to secure Indigenous rights, still requires translation and legal advice. The primary way in which access and benefit-sharing agreements are being articulated is through protocols (Raven, 2006). There remain significant concerns about unequal negotiating positions – not only between a community and a researcher/researchers, but also between a national government and a community. This is particularly the case because what is also being negotiated in this context is the recurring issue of sovereignty over land and hence biological resources.

New *Sui Generis* Legislation

Owing to the perceived difficulties of building new mechanisms that directly address Indigenous needs and expectations about knowledge use and control within the current intellectual property framework, suggestions for an altogether different approach have been made. *Sui generis* law means of its own kind; that is, it is a unique law complete unto itself and often created when current and existing laws are inadequate. (Examples of *sui generis* legislation in relation to traditional/Indigenous knowledge include the USA *Indian Arts and Crafts*

Act 1990; *Panama Law No. 20* (26 June 2000) and *Executive Decree No. 12* (20 March 2001). Another example of *sui generis* legislation relating to Indigenous rights is the Australian *Native Title Act* 1993 (Cth)).

A significant issue in this area is that Indigenous people must consistently be translating and transplanting their concepts into a framework of rights that are not necessarily appropriate or address the expressed needs. To the extent that Indigenous knowledge can be protected through laws of intellectual property, this is only possible through concepts including property, ownership, works, monopoly privilege, exclusive rights, originality, and individual authorship. Proposals for *sui generis* legislation for the protection of Indigenous knowledge and Indigenous rights are being slowly crafted. Countries like Peru and Panama have been at the forefront of developing national *sui generis* legislation. As Tobin and Swiderska comment:

> The role of a *sui-generis* regime could therefore be to establish a bridge between Indigenous/local community and national and international legal systems, in order to secure the effective recognition and protection of rights which derive from customary law and practice.
>
> Tobin and Swiderska, 2001: p. 47

There remains a range of questions about how *sui generis* legislation should be developed. For instance, is it appropriate for international agencies to assist in the development of *sui generis* legislation or should each nation state take responsibility for the development of a *sui generis* approach that is appropriate to the circumstances of each context? Other issues such as the diversity of subject matter, the difficulty of identifying owners/custodians and applicability, enforceability, and transferability across diverse cultural contexts raise challenges and responses to these will affect what approach is taken.

Traditional Knowledge Licenses and Labels

The Traditional Knowledge Licenses and Labels initiative takes its initial cue from the success of Creative Commons. (This initiative has been developed by Jane Anderson, Kim Christen, and Michael Ashley with initial support from the Canadian Social Science and Humanities Research Council *Intellectual Property in Cultural Heritage: Law, Policy, Ethics* Project, and the WIPO). Creative Commons harnesses the capacity of copyright owners to license their works. In providing more detail to the expectations and desires of copyright owners regarding the use of their works, users of copyright material are provided with more information that helps them make better decisions about the use of such works. This is also the point of departure for the Traditional Knowledge Licenses and Labels. In short, they are designed to address two key problems being experienced by Indigenous peoples in relation to the management of their cultural resources. Firstly, how to protect individual, community, and familial rights to knowledge according to community based rules and regulations while simultaneously enabling the sharing of that knowledge with others beyond the community. Secondly, how to create a new informational and educational paradigm for documented cultural materials that Indigenous peoples can no longer control – for example the extensive material produced through the colonial encounter that resides in the public domain.

Addressing these two issues constitutes the foundational aims and ambitions of the Traditional Knowledge Licenses and Labels initiative. They are not being designed to provide blanket licenses for all Indigenous or traditional knowledge – but rather licenses for very specific contexts and situations, especially where current license options like Creative Commons fall short. The Labels function as an educative strategy to help users make more informed decisions about material that might generically be deemed 'public domain' but that still has Indigenous rules and obligations about access and use. The initiative is developed as a twofold strategy because it is not just legal protection that is required, but mechanisms that facilitate and support the communities from which this knowledge derives and is transformed. The hope is that this initiative will contribute to a shift in attitudes, understanding, and behavior about what Indigenous peoples consider to be fair and equitable use of their knowledge resources.

Conclusion

> Although Indigenous peoples are now recognized as key actors in this global discourse, it will need to be expanded to encompass a wider range of principles and priorities, which will eventually encompass political commitment to indigenous people's rights of self-determination. Only when Indigenous peoples are full partners in this dialogue, with full juridical standing and only when their cultural world views, customary laws, and ecological practices are recognized as fundamental contributions to resolving local social justice concerns will we be engaged in anything we can genuinely call dialogue.
>
> Coombe, 2001: pp. 284–285

One of the substantive difficulties with this particular contemporary problem for law is that the issues are constituted through and by multiple discourses and historical moments – not all of which are located or properly accommodated (or recognized) within intellectual property law. This raises questions then about what intellectual property law is being asked to do and can reasonably achieve. It is not equipped, or even sufficiently self-reflective, to function as an agent of reconciliation. Moreover, intellectual property law poses specific kinds of problems for Indigenous people. Not only does it conveniently ignore its own role in the historical exclusion of Indigenous interests, but upon inclusion it demands that Indigenous people, as well as their cultural expressions, conform to normative identifications of liberal individualism, authorship, labor, property, creativity, identifications of what a work is, periods of protection, and the like. The incommensurability that this has produced exposes the differing cultural values regarding ownership, access, and control of knowledge that inform the law. Through the inclusion of this new 'subject matter' intellectual property law's own historical methods for justifying a 'right' in something that is intangible have become more visible. With Indigenous issues, the position and politics of 'culture' have become much more apparent, but it would be a mistake

to read the difficulties for law as only ones about the capacity of law to recognize culture and accommodate cultural difference (Anderson, 2009).

Questions around Indigenous knowledge protection are unlike any other issues that intellectual property law has had to consider. This is because Indigenous concerns stretch across every part of the intellectual property axiom. Issues can include legal questions involving copyright, patents, trademarks, designs, and/or confidential information. Moreover, how the problems manifest and are experienced are not always straightforward and often overlap into other areas of law, policy, and ethics. Therefore there is not yet an international consensus about how Indigenous rights to the protection of cultural knowledge systems can be secured, either within an intellectual property regime or through some other overarching legislative or policy framework.

Indigenous peoples are looking to this body of law for several interrelated but sometimes opposing reasons. Attention to intellectual property law is about both the way intellectual property law has been a tool to facilitate the exploitation and expropriation of Indigenous knowledge, wherein nonindigenous peoples become the owners, authors, and holders of property rights in Indigenous knowledge and how it can be used to protect and function as a tool of leverage to control Indigenous knowledge systems. To deal with both sides of intellectual property law – its historical use against Indigenous peoples and its contemporary use for Indigenous peoples – it requires understanding the history and inherent limitations as well as its potential in certain select circumstances.

Abstract

Philosophers of science, activists, and practitioners of indigenous knowledge have debated the status of indigenous knowledge with respect to science. 'Indigenous knowledge' is often used synonymously with 'local knowledge' or 'ethnoscience,' indicating knowledge specific to a culture. Science and Technology Studies scholarship, however, suggests that all knowledge, including scientific knowledge, is specific to its context. The study of indigenous knowledge has had practical results, shaping the politics of colonialism, nationalism, postcolonialism, and globalization. Issues at the intersection of science studies and indigenous knowledge, such as the imbrication of nature and culture, the construction of scientific certainty, and the historical contingency of systems of knowledge, have cultural and political implications for peoples negotiating their interrelationships in a globalized world.

Introduction: Convergence in Definitions

Science and Technology Studies (STS) and the study of indigenous knowledge are both interdisciplinary areas of investigation rather than singular disciplines. Their social and institutional origins were distinct, and early development in these areas occurred largely in isolation from each other. STS has disciplinary origins in history, sociology, policy, and philosophy, while the study of indigenous knowledge originated in anthropology and grew to overlap with agrarian studies and environmental history. Recent scholarship in both areas, however, suggests a convergence in their definitions of knowledge and their methodological assumptions.

'Indigenous knowledge' has long been associated with the terms 'local knowledge' or 'ethnoscience,' indicating knowledge systems that are specific to cultures or groups in particular historical or social contexts (see Richards et al., 1989). Adding the prefix 'indigenous' or 'ethno' to the terms 'knowledge' and 'science' often served to mark the embeddedness and context dependence of indigenous truths, in implicit contrast to the context-free, singular truth of science. The distinct meanings and uses of the terms 'indigenous knowledge' and 'science' both depended, thus, on a dichotomy that lay at the heart of modern definitions of knowledge, separating universal, value-free, static truth from situated, value-laden, changing cultural beliefs. Through the 1980s and 1990s, STS scholars questioned this dichotomy. They argued that all knowledge, including scientific knowledge, is specific to its particular cultural context. If this were correct, all knowledge might be considered 'indigenous.' The methods of study of the two fields should converge, then, since all knowledge should be studied with attention to its cultural and historical contexts. The distinct and separate foci of the two fields (science being conventionally studied in First World locations, and indigenous knowledge in the Third World) would then lose the logic of their original delineation. By the second decade of the twenty-first century, this blurring was evident, with anthropologists of science bringing 'indigenous' fieldwork experiences to First World laboratories, and sociologists of Euro-American techno-science extending their models to postcolonial contexts.

The status of the separation between 'indigenous' and 'universal' knowledge, the conditions of its construction, and the consequences of its erasure have long been issues of critical debate in STS. In a polemical and influential essay, *We Have Never Been Modern* (1993), Bruno Latour argued that if 'modernity' signifies the policing of boundaries between nature and culture, belief and reason, humans and nonhumans, then anthropological study reveals that we have never in fact been modern, for our practices have always involved hybrids of these categories. Latour and others, revisiting western knowledge from a distanced perspective, adopted and popularized ethnomethodological research. STS practitioners pictured the communities they studied as 'tribes' with characteristic beliefs and rituals. Western knowledge is, in this method of analysis, 'estranged' from its context or 'othered' (Douglas and Wildavsky, 1982). Conversely, nonwestern knowledges are presumed to be no less 'rational' or no more 'context dependent' than their western counterparts (Watson-Verran and Turnbull, 1995; Turnbull, 2000).

Studying the cultural and political role of scientific knowledge in different societies, scholars note that nature and culture are produced by networks of contingent histories; we encounter them not in their 'pure' states, but as hybrids –'socionatures' (Callon, 1995, p. 58) or 'natures–cultures' (Latour, 1993, p. 104). Anthropological observers of indigenous knowledge have always been interested in the ways in which boundaries were (or failed to be) drawn between nature and culture, and in the political weight of certain constructions of nature (see, for example, Lévi-Strauss, 1969). Late twentieth-century shifts in disciplines such as peasant studies, cultural geography and anthropology, and development studies also explored how ideas of nature shape and are historically shaped by social, political, and economic relationships (Peet and Watts, 1996; Bryant and Bailey, 1997). It became common to see interlinked analyses of the changing representations of nature, the production of ideologies of progress and modernity, and the functional relationship between the domination of indigenous groups and the production of scientific knowledge about them. The study of indigenous knowledge gradually shifted away from the province of primitivist ethnographers who tended to value it in opposition to science, assuming it to embody

primitive expressions of folklore that defy rationality and mythologize social relations.

Since the 1980s, anthropologists and interdisciplinary social scientists have viewed indigenous knowledge as coherent systems of belief and explanation that are homologous with scientific thought and that can often offer better accounts of local phenomena than those theorized by universalist science. This sort of investigation has prompted the reassessment of operative assumptions in medicine, pharmacology, resource management, and science education, as well as in nonscientific fields such as international law, policy, and development studies. Anthropologists, in the wake of postcolonial critiques of the imperial construction of ethnographic power, became increasingly self-reflexive and critical of their own representations of indigenous knowledge. Anthropological studies exposing ideological constructions of indigenous knowledge have become inseparable from efforts (in theoretical, pedagogical, and political realms) to alter power differentials in favor of marginalized groups. In the STS landscape at the turn of the twentieth century, histories of canonical European sciences (such as physics) began to share a common disciplinary space with the study of nonwestern knowledge.

Meanwhile, in the political sphere, the study of indigenous knowledge generated a host of policy implications, ranging from support for collective cultural rights and intellectual property rights for indigenous communities, to the reexamination of political assumptions about identity, modernity, and global citizenship. Nonwestern histories of the nineteenth and twentieth centuries, analyzed through the lenses of colonialism, nationalism, postcolonialism, and globalization, influenced both activism and scholarship on indigenous knowledge (Skaria, 1999; Sundar, 1997; Li, 1999). The study of indigenous knowledge facilitated, and in turn was enhanced by, the gaining of an influential international voice by indigenous rights groups and environmental nongovernmental organizations. These dynamics also helped shape emerging issues such as the politics of multiculturalism, the ownership of knowledge in the information economy, and the role of nationalism and group identity in a globalized world (Barker, 2011; Baviskar, 1995; Beteille, 1998). These are large, interdisciplinary topics in themselves, but even as they grow wider in scope and diffuse in their disciplinary underpinnings, the issues raised by the study of indigenous knowledge continue to intersect with questions about the authority of science and its representations of nature, about the politics of science and technology as interpreted by international institutions and policymakers, and about the role of technology and development in the forging of a more equitable world. In proportion to the seriousness with which it has grappled with these disparate discourses, STS research has yielded both theoretical insights and practical results.

Theoretical Results: Indigenous Knowledge and Epistemology

Epistemological concerns are central to the study of indigenous knowledge. Scholars of indigenous knowledge argue that if we take nonwestern knowledges seriously, we are quickly led to abandon a naïve realism with respect to scientific truth. That is, if we investigate indigenous knowledges for their internal coherence, social role, and explanatory power, rather than as instances of nonrational narratives, then we accumulate strong support for the argument that explanation, evidence, and truth are socially constructed and context dependent. This suggests, one argument continues, that what we see in the world, within and among cultures, are competing rationalities, rather than a singular mode of rationality and reason (commonly held to be the province of the west, and its sciences), versus nonrational or mystical modes of thinking that are antithetical to science (commonly held to be found outside the west). Such an argument requires a complex and situated definition of rationality, rather than a simple one assessing syllogistic consistency or the efficient choice of technical means for particular instrumentalist ends (Wilson, 1970; Sen, 2000).

Disagreement persists about how best to characterize indigenous rationalities with respect to western science, as illustrated in a well-known debate between anthropologists Marshall Sahlins (1995) and Gananath Obeyesekere (1992). Sahlins, holding that different cultures possess different rationalities, suggested that anthropologists ought to cultivate a "regard for cultural difference" (p. 14). He called on anthropologists to respect the worldwide resurgence of particular cultures as "distinct forms of life" (p. 13) and to value their opposition to a dominant, utilitarian, western modernity. In his own work, Sahlins suggested that Hawai'ian thought, for example, does not distinguish the practical from the mythical, nor the observable from the fictional, although these oppositions characterize European epistemologies (p. 6). Gananath Obeyesekere challenged this view, maintaining that all cultures possess a 'practical rationality' – that is, a flexibility and creativity expressed through manipulating and interpreting the world (p. 19). Obeyesekere's interpretation of Hawai'ian history via the attribution of a 'practical rationality' to the Hawai'ians was, in Sahlin's view, an example of 'symbolic violence' to the culture, and amounted to a neocolonialist model that reduced all cultural practices to western logic and rationality (p. 14). Obeyesekere contended that the cross-cultural interpretation of practical rationality, although complex and difficult, is "necessary if one is to talk of the other culture in human terms" (p. 21).

More recently, Eduardo Viveiros de Castro has suggested that the terms of the debate be shifted away from the realism/relativism argument. Arguing, through Amerindian cosmologies, for 'multinaturalism' and 'perspectivism' to replace multiculturalism, he insists on retaining difference and incommensurability, but on refusing the "relativism [which] is often implied in the ethnographic characterization of Amerindian cosmologies" (Castro, 2004b, p. 471). Castro argues that "Amazonian ontologies postulate difference rather than identity as the principle of relationality" (Castro, 2004a, p. 18). The task of translation, he suggests, involves an equivocation that is at the heart of relationality – a task whose inaccuracies and contingency we should embrace, rather than seek to erase. "Anthropology, then, is about misunderstandings," suggests Castro (2004a, p. 11). His advocacy of Amerindian perspectivalism takes him closer to a Deluezian than a Latourian position:

> Because there are no points of view onto things, things and beings are the points of view themselves (as Deleuze would say, 1988: 203). The question for Indians, therefore, is not one of knowing

> "how monkeys see the world" (Cheney and Seyfarth, 1990), but what world is expressed through monkeys, of what world they are the point of view. I believe this is a lesson from which our own anthropology can learn.
>
> Castro, 2004a, p. 11

Rather than view STS or anthropology as saving indigenous knowledge from obscurity, a range of new work from the perspective of indigenous practices has suggested that we could transform our disciplinary discourses by taking seriously the possibility of incommensurable ontologies and natures. Initially central to STS scholars' focus on epistemology, indigenous knowledge later became a window to new questions about ontology. It is key to an emerging emphasis in twenty-first-century STS on thinking through things and exploring pluralist, historically shaped ontologies (Henare et al., 2006).

Practical Results: Indigenous Knowledge and Politics

The categories of these theoretical debates recur in the realm of activism. For example, many activists, from Canada to India, have found it useful to employ a relativist argument that rejects the subordination of indigenous knowledge to science, while retaining the postulate of incommensurable difference. That is, they value indigenous knowledge over scientific reason, arguing that narratives of re-enchantment are needed to restore the integrity of indigenous cultures, lost or rendered inauthentic through violent encounters with European Enlightenment science. This position sees an incommensurability between tradition (seen as authentically indigenous) and modernity (seen as ethnocentrically European). Although phrased in the vocabulary of the anticolonial struggle, it is reminiscent of eighteenth- and nineteenth-century Euro-American romanticist and primitivist discourses in its desire to value a nature-centered spirituality over a technicist instrumentality. In both industrialized and developing countries, however, romantic and biocentric attempts to preserve the authenticity of indigenous knowledge have been critiqued from perspectives suspicious of epistemological relativism and biocentric romanticism.

Take, for example, the diversity of arguments from India. STS scholar Meera Nanda, supporting practical, rational 'people's science' movements in India, argues that the nostalgia for authentic indigeneity has oppressive overtones of nativism and cultural nationalism (Nanda, 1997). Anthropologist Akhil Gupta acknowledges the legacy of romanticism, but also links its persistence to the efficacy of political tactics: "the effectiveness of 'indigenous' identity depends on its *recognition* by hegemonic discourses of imperialist nostalgia, where poor and marginal people are romanticized at the same time that their way of life is destroyed" (Gupta, 1998, p. 18). Sociologist Amita Baviskar points out that these political tactics could shift historically. Observing changes in central Indian tribal and indigenous politics from the 1990s to the 2000s, she observes that, as the idea of cultural rights to specific lands was legislatively marginalized, the new politics of Hindu nationalism offered an alternative: "Adivasis could now imagine themselves as part of a larger cultural landscape – the Hindu nation, rather than as a subaltern presence incarcerated in a state of nature" (Baviskar, 2005, p. 5110).

Analyzing the politics of indigeneity, political scientist Ronald Niezen argues that, rather than signifying primordial identities, the category of indigenous people should be understood as a recent, historically shaped one (Niezen, 2000, p. 121). It may be understood through another growing subfield in STS: the histories of resource extraction, bioprospecting, and transnational economics (Li, 1999, 2000).

The notion of indigenous knowledge holds practical allure for biotechnologists, who believe that local knowledge of nature might hold the key to decades of future research into medicine and pharmaceuticals. It represents an ethical dilemma for the architects of globalization, heavily criticized for seeming to obliterate diversity in the interest of a homogeneous and efficient global marketplace. Advocates of indigenous knowledge often use the term synonymously with 'eco-friendly' or environmentally correct knowledge. But, as diverse studies show, the term 'indigenous people' has a somewhat diffuse reference and can range from small peasants, linked to domestic and global markets, to tribes, isolated from other groups.

In the last two decades of the twentieth century, there was a surge in support, from many different interest groups, for indigenous peoples' rights to their knowledge, resources, and cultural practices. Historical changes have often altered indigenous communities' relationship with their environment, or altered the environment itself, so that methods once sustainable might not be so in a changed context. Nor are all indigenous communities necessarily committed to preserving natural environments. For example, the Kissia of the Republic of Guinea, who use forest resources, tend to conserve forest growth, while other tribes in the same region, who are not dependent on trees for their survival, try to reduce forest growth wherever possible (Fairhead and Leach, 1997).

Practical struggles facing indigenous communities have often involved rights of access to water, fuel, and other elements of their natural surroundings that are crucial to their survival. Globally successful activism in the 1990s defended the rights of indigenous people to manage their natural surroundings independently from 'top-down' projects that seek to impose universalist models of productivity and resource management. In these arguments, indigenous knowledge was seen as having both cultural and pragmatic significance. The state and the global economy, representing hegemonic modes of resource extraction and cultural homogenization, were often seen as antagonistic to the interests of indigenous communities. Summing up the importance of law, politics, and the state in understanding the category of indigenous people, Ronald Niezen noted, "Although referring to some three hundred million original peoples worldwide who maintain attachments to 'timeless' original traditions, the political reality of 'being indigenous' is a product of the past several decades, originating in the terminology of international law and broadening to become a new form of group identity" (Niezen, 2000, p. 120).

Studying Indigenous Knowledge in Historical and Ecological Context

Antagonism between the state and indigenous communities dates back to the colonial era, when the expansion of European

territories was in large part an effort to control not only more markets and labor power, but also natural resources. Colonial environmental management often met with strong resistance from indigenous communities whose control over their environment was weakened or destroyed by colonial policies (Ranger, 1989; Peet and Watts, 1996). Soon after the mid-twentieth-century's wave of decolonization, in the 'development decades' of the 1960s, postcolonial nations struggled to catch up with the productivity of the industrialized west. Postindependence development involved, in many countries, shifts in economic policy to maximize resource extraction for exports, large conversions from food crop to cash crop cultivation, and increasing industrialization. The implementation of these policies (advocated by large international development agencies such as the World Bank) often caused growing pollution problems and the depletion of soil, water, and other natural resources. This most dramatically affected small farmers and indigenous groups, displacing them from their livelihood and threatening their modes of survival. Indigenous environmental movements, such as the antidam movement in India's Narmada valley, have often characterized the World Bank and the postcolonial nation-state as perpetuating colonial exploitation by subordinating local knowledge and experience to the rationalizing forces of science and economics (Rich, 1995; Scott, 1998).

The rapid growth, through the 1970s, of environmental ethics and economics did not always bring support for indigenous communities (see Harvey, 1996). Neo-Malthusian and neo-Hobbesian ecological scholarship identified overpopulation, poverty, and weakly governed communities as responsible for much environmental degradation and led to policies promoting the privatization of common property or advocating a global Leviathan. Influential theorists such as Garrett Hardin and William Ophuls predicted that the combination of resource scarcity with social complexities would lead to an ecological crisis (Hardin, 1968; Ophuls, 1977). Many saw these looming crises as legitimating more authoritarian state-led solutions, giving primacy to private property and modern resource management techniques. Since most indigenous communities are not affluent and are dependent on jointly governed common resources, these theories often pitted them against the prevailing expert wisdom.

Hardin's 'tragedy of the commons' thesis spurred detailed studies of indigenous environmental knowledge, increasingly critical of Hardin's assumptions. New scholarship on the commons, combining historical and political economic analysis of ecology, discovered empirical evidence that commons use did not inevitably lead to tragedy (Ostrom, 1990; Carney, 1996). Indigenous use of commons land was found to be more complex than simply opening access to all users, including irresponsible 'free riders.' Research in diverse communities found that successful commons use was invariably tied to complex, differentiated sets of communities with separate but overlapping rights and responsibilities, facilitating individual as well as group uses of lands and resources. In order to recognize and maintain these delicate social relations of resource use, both indigenous participants and outside administrators needed to be aware of the complexities of social stratification, and historical changes in social relationships among indigenous communities, and between them and the state. In many developing countries, however, colonial and postcolonial administrations altered the meanings of land-holding and resource use traditions through successions of new legal definitions and administrative hierarchies, over time squeezing indigenous systems into models that privileged private over communitarian interests. Histories of disparate indigenous groups reveal a continual flux of local, regional, and global knowledges and practices, rendering unviable nostalgia for a pure localism, or notions of pristine authenticity (McCay and Acheson, 1987). An emerging field of 'Third World Political Ecology' argued that support for rights of indigenous peoples should be inseparable from the development of more nuanced historical analyses of environmental and social relations.

Since the 1980s, the importance of indigenous knowledge has been widely acknowledged by influential international institutions. In 1982, recognizing that disparate indigenous movements all over the developing world were articulating concerns similar to each other, the United Nations established the Working Group on Indigenous Populations, annually bringing together participants from indigenous communities around the world. Indigenous groups, working in solidarity with each other and developing an international alliance facilitated by the annual working group meetings in Geneva, prepared a joint statement for the 1992 Earth Summit at Rio, asserting indigenous rights as a fundamental requisite for the future of sustainable development. Recognizing the growing importance of biotechnology and its links with traditional knowledge of medicinal plants, it stated: "[W]e demand guaranteed rights to our intellectual property, and control over the development and manipulation of this knowledge" (Article 44, Charter of the Indigenous-Tribal Peoples of the Tropical Forests, reprinted in International Alliance of Indigenous-Tribal Peoples of the Tropical Forest and the International Working Group for Indigenous Affairs, 1996, p. 9).

The 1993 UN Declaration on the Rights of Indigenous Peoples recognizes indigenous peoples' rights to the preservation of all forms of their knowledge, including cultural, spiritual, medical, scientific, and technological. It also recognizes the right of indigenous peoples to protect their intellectual property, and to the restitution of any such property that was taken from them in violation of their laws or customs. In 1998, the World Intellectual Property Organization established the Global Intellectual Property Issues Division, recognizing indigenous peoples as the 'most important' beneficiaries of intellectual property (Roulet, 1999, p. 129).

The successes of indigenous peoples' movements in the late twentieth century were accompanied by a popularization, at both expert and lay levels, of the terms and categories of 'indigeneity.' These successes were linked, paradoxically, to a tendency critiqued by political ecologists. Critics pointed out that increased funding for the protection of indigenous groups often went along with romanticized descriptions of such groups. In a study of South Asian environments and ethnicities, Sumit Guha suggested that the 'poetic vagueness' in the definitions of indigenous groups feeds into a tendency to regard such groups as static remnants of original racial groups, supporting policies that seek to preserve them as museumized 'endangered species' (Guha, 1999, pp. 4–5). Anthropologist Lisa Malkki has critiqued the 'sedentarist metaphysics' of indigeneity for essentializing,

rather than historicizing, the link between indigenous people, knowledge, and land (Malkki, 1992).

International recognition and support for indigenous knowledge grew dramatically through the new millennium. Nevertheless, as conflicts between indigenous rights and international trade grew rather than diminished, it remained to be seen how far courts would go to enforce 'soft law' elements such as international conventions, to impose regulations on transnational corporations and states, protecting indigenous communities. The future of indigenous knowledge in this age of globalization may well be worked out in policy debates and resource conflicts rather than in philosophical texts. There will always, however, be an important link between academic and political life in this area. Interpretations of the various assumptions in environmental law and the indigenous knowledge will depend on real-world manifestations of the construction of scientific uncertainty, the historical contingency of systems of knowledge, the historical ontologies, and social epistemologies of nature and culture. In this way, the theory and practice of STS and indigenous knowledge may become more closely interlinked and may have significant consequences for the shape of future transnational indigenous worlds.

Indigenous Management Styles

Abstract

Examples of indigenous perspectives infusing management practices and research are scarce in the mainstream management literature. This article summarizes different approaches to defining indigenous, provides examples of indigenous management perspectives, and describes the concept of indigenous capitalism. Collectively the article demonstrates the diversity of philosophies underpinning management practice and highlights opportunities for advancing management theory and practice by including indigenous research approaches, knowledge, and practices.

Given the vast international literature on management and global market practices, one could be forgiven for thinking that our understanding of non-Western concepts of management was well formed. Quite the opposite is true, however, with Western perspectives embedded in colonial traditions prevailing (Holtbrügge, 2013; Rodrigues et al., 2012; Suddaby et al., 2011; Verbos and Humphries, 2012). Although the need and the legitimacy of indigenous management theory and practice is contested by some, there are a growing number of voices calling for research on indigenous management practices and the use of indigenous knowledge and research approaches to build new management theory (Leung, 2012; Pio et al., 2013; Suddaby et al., 2011). Advocates' rationale for embracing indigenous perspectives on management is illustrated by this quote from Marsden in 1991 (p. 32, cited in Holtbrügge, 2013, p. 2): "strategies based on European scientific techniques ignore the rich resources, both practical and intellectual, which exist in non-Western societies (…). 'Local', 'traditional' or 'folk' knowledge is no longer the irrelevant vestige of 'backward' people who have not yet made the transition to modernity, but the vital well-spring and resource bank from which alternative futures might be built."

Notions of Indigenous

The term indigenous is used in several different ways in the academic literature (Jackson, 2013). As noted by Van de Ven and Runtian (2012), the meaning of indigenous is culturally sensitive and has many possible definitions, but all referencing in some way belonging to, originating from, or identifying with a specific people or place. Scholars such as Van de Ven and Runtian (2012) take a broad view of the term, arguing that all research and practice is indigenous in that they emerge from a specific culture and context. Others reserve the term indigenous knowledge, indigenous research, and indigenous management for that which relates to first nations peoples (e.g., Bunten, 2011). Still others use the term indigenous to refer to the cultural, historical, and ideological traditions of non-Western contexts. The United Nations Permanent Forum on Indigenous Issues defines indigenous as "peoples who are the inheritors and practitioners of unique cultures and ways of relating to other people and to the environment" (UNPFII, 2007). Using this definition, they identify "more than 370 million indigenous peoples in some 90 countries worldwide" (UNPFII, 2014).

Examples of Indigenous Management Perspectives

Regardless of which definition of indigenous we adopt, it is useful to acknowledge the synergy between Eastern and indigenous traditions of wisdom, interconnectedness, and holism (Holtbrügge, 2013; Pio et al., 2013). These notions in particular have been drawn on by scholars to argue that management theory and practice would be strengthened by connecting the traditional notions of wisdom associated with indigenous and Eastern traditions with the economic focus of Western management perspectives (Pio et al., 2013). Examples of indigenous management perspectives are informative in differentiating indigenous ideology from Western ideology as well as identifying possible bridges between the two worlds.

Like all indigenous peoples, Australian Aboriginal peoples hold a relational view of the world whereby they recognize themselves and their place as part of a greater cosmology in which all creation is purposeful and interconnected as kin (Miley and Read, 2013; Royal, 2002). Relational knowledge accepts there are different points of view and allows differences to coexist in an atmosphere of trust, collaboration, and respect (Verbos and Humphries, 2012). A focus of indigenous management practices therefore is on inclusion and valuing all employees' contributions as equally worthwhile (Miley and Read, 2013). The relational perspective is also evident in traditional problem-solving processes, which involve the whole kinship structure, including children, in a public discussion (Pearson and Chatterjee, 2010). Face-to-face decision-making that openly considers and balances the views of work, family, and community is a common hallmark of indigenous management practices in Australia (Pearson and Chatterjee, 2010).

Australian Aboriginal peoples' traditional thinking style has been described as patterned in contrast to Western triangulated thinking which is based in an ideology of hierarchy and power, where success is defined according to monetary wealth, property, rulership, and ownership (Miley and Read, 2013; Pearson and Chatterjee, 2010). Pattern thinking refers to viewing

everything as interconnected and belonging within the larger pattern of the universe (Miley and Read, 2013). Accordingly, Aboriginal law promotes harmony, bonding all things together in equal relationships. Likewise, their belief systems are centered on universality, kinship, and 'country' (Miley and Read, 2013). The notion of 'caring for country' is a manifestation of pattern thinking and leads to indigenous management practices associated with inclusion of environmentally responsible outcomes in key performance indicators (Miley and Read, 2013).

The violent colonization of Australia displaced its traditional Aboriginal peoples physically, spiritually, culturally, and psychologically (Appo and Härtel, 2003, 2005). The associated cultural upheaval is manifest in identity confusion, loss of traditional languages, and disintegration of cultural traditions (Appo and Härtel, 2003, 2005). To illustrate, of the 250 languages spoken preinvasion, just 60 remain as a living language (Korff, 2014). Moreover, in 2008, just 62% of Aboriginal adults reported identifying with a clan, language, or tribal group (Korff, 2014). The result is a complex and heterogeneous picture of contemporary Aboriginal peoples, where, in many instances, only fragments of traditional connections to people, place, and language remain, and personal experiences and ways of life vary. The implication of this is that not all Aborigines identify or follow an indigenous perspective.

In general terms, an Aboriginal worldview shares the focus on relatedness of other indigenous perspectives. All aspects of reality, past, present, and future, are viewed as interlinked with one another and to a spiritual world (Miley and Read, 2013). Thus, all of creation is shared and all is for the benefit of others in the relationship. One cannot simply take, therefore, one must ensure that what one takes is transformed into benefit for others and sustaining positive relationships. As summarized by Roy (2014, p. 118), "Aboriginal worldviews are characterized by their relational, communalistic, eco-centric and cosmo-centric focus."

A number of lessons can be drawn from examining the interface of European management practices with Aboriginal worldviews. First, indigenous management practices not only reflect a particular indigenous worldview; in today's world they almost always must operate within the parameters established by a larger economic system founded on strikingly different cultural assumptions. Thus, to engage in indigenous management practices also requires cross-cultural competencies on the part of indigenous and nonindigenous practitioners (Farrelly and Lumby, 2009). Across a range of discipline areas, there is consensus that these competencies include enacting cultural sensitivity, cultural awareness involving an understanding of Aboriginal history and philosophy as well as one's own culture and views of Aboriginal people (Sue, 2006) and the concept of cultural safety. The latter is especially critical in that it creates "an environment that is spiritually, socially and emotionally safe, as well as physically safe for people; where there is no assault challenge or denial of their identity, of who they are and what they need. It is about shared respect, shared meaning, shared knowledge and experience of learning together" (Williams, 1999). Too often, indigenous people's nonindigenous counterparts lack an accurate understanding of their culture and history. To illustrate, recent figures estimate that 91% of white Australians have little to no contact with Aboriginal people, with the majority citing the media as their sole source for developing impressions of Australian Aboriginal peoples (Moreton-Robinson, 2011, cited in Duthie et al., 2013). Genuine contact and experience with Aboriginal peoples is essential to develop accurate cultural knowledge.

A second lesson relating to interfacing indigenous and nonindigenous business practices is recognizing that "it is an economic imperative … for businesses to identify the ways in which traditional culture can be integrated into their organizational practices, such as in the community consultation processes …" (Härtel et al., 2013, p. 540). For example, to respect cultural norms of involving all community members, a business would adopt extended decision-making time frames. Also, to integrate the Aboriginal relational worldview, nonindigenous businesses would focus on building and sustaining long-term mutually beneficial partnerships where the indigenous stakeholder is not only the specific indigenous business partner, but also the larger Aboriginal community of which it is a part (Härtel et al., 2013). This represents a real shift for most nonindigenous organizations in that it means human resource management activities must not just be internally focused, but also must be externally focused on communities, and that a lifespan view of the employment process be taken (Härtel et al., 2013, p. 538). Thus, competencies in community relations and community development are essential features of nonindigenous organizations that work respectfully and effectively with indigenous organizations (Härtel et al., 2013). It means adopting "a view of social inclusion as incorporating community consultation in corporate activity from pre-entry to exit, good corporate-community relations, community self-determination, and promotion of community and regional sustainability" (Härtel et al., 2013, p. 538). Further, the considerable funds provided to support Aboriginal employment and businesses within the Australian context has led to new forms of exploitation that need to be guarded against, for example, tokenism. An example of this is the organizations that pose as Aboriginal organizations when in fact they do not represent Aboriginal economic and cultural interests. Again, working closely with Aboriginal communities and respecting their cultural authority and rights to self-governance addresses this issue by letting them identify which claimants are indeed Aboriginal organizations (Härtel et al., 2013).

Illustrative of pattern thinking, the Māori worldview, termed *Te Ao Māori*, is one of interconnectedness between the physical and the metaphysical. The relational perspective in Māori businesses in New Zealand encompasses values of respect, care, well-being, and high-quality relationships (Spiller et al., 2011). These traditions are referred to as *Kaupapa Māori*, or 'the Māori way' (Ruwhiu and Cone, 2013).

A core Māori value is *kaitiakitanga* or stewardship, where humans are born with the obligation and power to create *mauri ora* or well-being for all (Spiller et al., 2011a,b). *Mauri* refers to the spiritual life force that is seen to exist in all aspects of creation and humans have the purpose and agency to care for and conserve it (Spiller et al., 2011). This perspective places humans in a reciprocal relationship with others, the spiritual, the ancestral, and the environmental and thus one's own well-being is inextricably linked with the well-being of all the others in the relationship (Pio et al., 2014;

Spiller et al., 2011a,b). Accordingly, the Māori view business as having the goal of creating well-being (*mauri ora*), which includes "healing and sustaining life" (Spiller et al., 2011, p. 225). Thus Māori organizations are differentiated from organizations founded in the Western individualistic philosophy in that they see "profit and economic well-being as a means to serve broader social, cultural, environmental, and spiritual well-being goals" rather than as an end in themselves (Spiller et al., 2011, p. 225).

Springing from the focus on relationships, Māori management practices prioritize relationships, operating from the stance that "You do business because you've got a relationship. The relationship leads to business" (Ruwhiu and Cone, 2013, p. 32). The focus on relational well-being and wealth provides a unique competitive advantage for Māori organizations in the areas of "forging long-term supplier arrangements and joint venture partnerships with other global firms" (Spiller et al., 2011, p. 224). Moreover, the Māori holistic philosophy of interconnectedness and well-being in and through relationships manifests in corporate social responsibility as a deeply embedded and central value.

Māori organizations ensure culturally relevant management practices by focusing on relational processes. Management decisions are assessed according to Māori values, most notably respect (*manaaki*), empathy (*aroha*), fostering unity (*kotahitanga*), stewardship of resources (*kaitiakitanga*), seeking knowledge and understanding (*mātauranga*), just behavior (*tika*), relational/interconnected view of all creation (*whakapapa*), and uplifting others (*hāpai*) (Spiller et al., 2011).

In Chinese indigenous research, one of the central concepts is the Confucian notion of ethics (Pan et al., 2012). This perspective reveals a relational view of ethics where people are viewed as sacred which creates respectful relations and participation in rituals is seen as key to civility (Kim and Strudler, 2012). Other Chinese indigenous concepts receiving growing attention in the management literature are *guanxi* (good relationships) and *xin* (mutual trust), both of which derive from the Confucian tradition of reciprocity (Härtel et al., 2010; Pan et al., 2012). The type of relationship it entails is an instrumental one, involving the repeated and reciprocal exchange of favors with members of the significant groups to which one belongs (Härtel et al., 2010; Jiang et al., 2013). Guanxi emerges and is maintained through the continual demonstration of *xin* (trust) and *xinyong* (trustworthiness, credibility, reliability, and reputation) in one's network (Härtel et al., 2010). Managerial *guanxi* practices have been separated into *inward guanxi practices* and *outward guanxi practices* to reflect differences in managers' use of their guanxi ties to bring resources into their organization as a result of favor receiving or moving resources outward as a result of favor giving (Jiang et al., 2013).

The indigenous concept of *ubuntu* is frequently evident in management practices in South Africa. The Bantu word *ubuntu* conveys a relational perspective where people are bound together as is their well-being (Holtbrügge, 2013). Like the traditional decision-making practices of Aboriginal Australians, *ubuntu* emphasizes community participation and consensus in decision-making.

The Hindu concept of *vanaprastha ashrama* manifests in the service orientation, social responsibility, and focus on a purposeful life of managers in India (Cappelli et al., 2010). Stemming from the Vedic religion, the concept of *lokasangraha* or 'prosperity for all' underpins Vedic economic philosophy, which focuses on harmony, cooperation, and frugality. The Hindi concept of *jugaad* refers to the mentality of improvising when resources are lacking or obstacles are encountered (Cappelli et al., 2010).

Indigenous Capitalism

The fundamental features that differentiate indigenous corporations and capitalism from other forms are the embedding of indigenous values, law, culture, and community accountability into the corporate mission and business culture of the organization (Bunten, 2011). Indigenous capitalism therefore is defined as the accumulation and redistribution of wealth by indigenous corporations within indigenous communities, with ecological, social, spiritual, and cultural stewardship as the overarching objective (Bunten, 2011; Spiller et al., 2011). Indigenous capitalism prioritizes relationships with people and the environment, emphasizing stewardship and sustainability rather than economic growth (Spiller et al., 2011). The development of indigenous corporations has been described as a means for indigenous groups to participate in global and political economies while investing in their own communities, land, and governance (Bunten, 2011). The relational logics of indigenous perspectives share with liberal feminist perspectives an emphasis on relationships, relational processes, and ethics (Verbon and Humphries, 2012). Relational logics may provide the foundation required to transform institutions from promoting marginalization and discrimination to encouraging inclusiveness, integrity, and justice (Verbos and Humphries, 2012).

Conclusion

Indigenous management practices are embedded in traditional or local knowledge, and as such have long been marginalized in a Western dominant management literature (Nkomo, 2011, p. 378). They are necessarily context and culture bound, which is not to say they do not change or cannot generalize (Leung, 2012). Most importantly to the identification of indigenous management practices is participation of those deemed as indigenous so that descriptions and theories are tied to the people, their place, and the time, and overgeneralization is avoided (Appo and Härtel, 2003; Holtbrügge, 2013). Ultimately, the advancement of management practices and theories depends on decolonizing the management literature so that Western philosophies and methods are not privileged, portrayed as superior, or playing the role of enlightening the rest of the world.

Indigenous Psychology

Rogelia Pe-Pua, University of New South Wales, Sydney, NSW, Australia

Abstract

Indigenous psychology (IP) is both an approach or perspective and a movement in psychology. There have been several attempts to define it. The core elements of this approach are indigenous cultures used in explaining behavior and mental processes, using indigenous interpretations, and discovery or revalidation of psychological concepts and theories that emerge from within the culture. These concepts and theories may not necessarily have emerged or been emphasized in current psychological literature that has been pointed out as having a predominantly North American or European character or 'bias.' This article will examine the different definitions of IP, and outline its main features. It will outline the historical background of the perspective and movement, followed by a portrayal of the development and current status in the main societies where this has advanced significantly. Particular attention will be given to contributions to theory and methods. The article will end with an outline of ongoing debates, future prospects as well as challenges for IP.

Definition of Indigenous Psychology

Indigenous psychology (IP) is both an approach or perspective and a movement in psychology. It has been defined by a number of scholars, most of whom were the founders of the IP movements in their respective countries. Here are key examples of how IP was defined:

Psychology that is anchored on the thought and experience of the indigenous people, as understood from an indigenous perspective (adaptation from the Philippines' Virgilio Enriquez's definition of *Sikolohiyang Pilipino*, the Philippine IP, 1975).

Culturally appropriate psychology, or a route to 'appropriate' psychology (Japan's Hiroshi Azuma, 1984: 53).

"Psychological knowledge that is native, that is not transported from another region, that is designed for its people. In other words, indigenous psychology is understanding rooted in a particular sociocultural context" (South Korea's Uichol Kim, 1990: 145).

Psychology that emerges from cultural tradition; lies in daily, mundane activities of people; understands and interprets in terms of indigenous and local frames of reference and culturally derived categories (Berry et al., 1992: 380–381); and embodies psychological knowledge that is relevant and is designed for its people – reflecting the sociocultural reality of its society (India's Durganand Sinha, 1997: 132).

"Various definitions express the same basic goal of developing a scientific knowledge system that effectively reflects, describes, explains, or understands the psychological and behavioral activities in their native contexts in terms of culturally relevant frames of reference and culturally derived categories and theories" (Taiwan's Kuo-Shu Yang, 2000: 245–246).

Denotes three distinct phenomena: (1) the actual culturally organized psychology of an individual, (2) the local understanding of an individual's psychology, and (3) cultural–psychological theory and methodology (Ratner, 2008).

A number of elements of IP can be drawn from these definitions, for example:

Primacy of the indigenous or local or culturally derived perspective, understanding, categories, interpretation, explanation, frames of reference.

Relevance to the indigenous/native culture/people, reflecting their sociocultural reality.

The indigenous culture as the source of concepts and theories, rather than a set of imposed theories and knowledge.

'Indigenous compatibility,' which refers to the extent by which "the researcher's concepts, theory, methods, tools, and results adequately represent, reflect, or reveal the natural elements, structure, mechanism, or process of the studied phenomenon embedded in its context" (Yang, 2000: 250).

A movement or potentially a discipline.

The development of IP as a movement in various regions of the world was the subject of a survey conducted by Allwood and Berry in 2006. Their article included 15 contributions that focused on global development and characteristics, country development and local characteristics in each of the countries that they surveyed. They provided the following useful summary (abstract):

> Post-colonial reactions to mainstream psychology, and the belief that it was not an efficient aid to solving local social problems, were seen as important reasons for developing IPs. IPs were generally seen as attempts to produce a local psychology within a specific cultural context. Different views about what methods are legitimate in IPs were present (from experiments to various more 'humanistic' methods). IPs were commonly seen as being able to open up, invigorate, and improve mainstream psychology. The style of theorizing in the IPs was felt by many to be to build theories from the 'bottom up' on the basis of local phenomena, findings, and experiences. Some contributors saw the IP as a kind of cultural psychology, and a few noted that IP and cross-cultural psychology have an interactive mutually enriching relationship. Nearly half of the contributors emphasized the critical reaction to their work on IP by colleagues working more in the line of mainstream psychology. Many contributors felt that IP could contribute to the development

> of a more general universal psychology. Different indications of heterogeneity in the IPs were found among the contributors, for example, with respect to the role given to religion in the local IP. Sometimes the presence of different IPs within the same country was reported. This also indicates heterogeneity in the IPs.
>
> Allwood and Berry, 2006: 243

The term 'Indigenous psychology' begs the question, "What is the indigenous in indigenous psychology?" Borrowing from the attempt of Enriquez to clarify this during the early days of IP in the Philippines, it is possible to clarify three uses of 'indigenous': *Indigenous psychology* refers to psychology that is anchored on the thought and experience of the indigenous people, as understood from an indigenous perspective. *Psychology of the indigenous people* refers to any analysis of psychological behavior of the indigenous people, whether from an indigenous perspective or not, i.e., whether using indigenous or nonindigenous theories and methods. *Psychology in the indigenous country or culture* would then refer to the development of psychology in the particular culture or country, embodying both indigenous and nonindigenous perspectives and research.

But the term 'indigenous' needs further elaboration. Indigenous Maori (from New Zealand) psychologist Linda Nikora and her colleagues (in Allwood and Berry, 2006: 254) gave two meanings for the term 'indigenous': (1) Fourth World peoples (Nikora et al. (in Allwood and Berry, 2006: 254) referred to "Fourth World nations, defined here as indigenous communities positioned within First and Second World nations, for example, Hawai'ians, Aboriginals, and Maori – the original inhabitants of the lands in which they dwell."); and (2) all peoples residing in a society. In countries such as Australia, New Zealand, and Canada, there are distinct and widely recognized/acknowledged Indigenous peoples who are the first inhabitants of the land. In these countries, the word 'Indigenous' (with a capital 'I') in IP clearly refers to these peoples. On the other hand, in countries such as the Philippines, China/Taiwan, and India, 'indigenous' in the term IP refers to the people residing in those societies. The term has also come to be used in contrast to the 'exogenous' (that is, theories and methods that have been imported from the West). This has to be understood in terms of a historical background of colonization that these countries underwent (by Spain, Japan, and the United States in the case of the Philippines; by British rule in the case of India; and academic colonization by the West in the case of all the three countries).

Indigenization

IP as a movement has been referred to as the "indigenization movement in psychology" (Hwang, 2013: 716), which Hwang traced back to Wilhelm Wundt and his first laboratory at Leipzig in 1879. D. Sinha (1997) defined indigenization as the process of developing IP, the process or the strategy for obtaining an IP. This process evolves through stages, beginning with an acknowledgment of the limitations of Western theories and methods, which are then corrected by adapting them to suit local realities, or through the discovery of indigenous concepts and methods arising from the local culture.

Adair (2006) also talked about stages, identifying indigenization as one of the four stages in the development of IP: importation, implantation, indigenization, and autochthonization. "Autochthonization refers to the processes leading to the emergence of a self-perpetuating discipline independent of its imported source, the culmination of the indigenization process" (p. 472).

Pickren (2013) defined indigenization as "the process whereby a local culture or region develops its own forms of knowledge and practice, either by developing them from within that culture, or by importing knowledge and practices developed elsewhere and combining them with local concepts" (p. 698). Pickren argued that "American psychology was indigenized from German, French, and English developments that were imported to North America and mixed with home-grown metaphysics, religion, and healing practices (e.g., mesmerism), each of which has its own history of indigenization" (p. 698). And this North American (indigenous) psychology was and continues to be dominant in the training of psychologists in many Asian and African countries that lead many to experience the lack of fit to their own cultures. Because of this, they "began a self-conscious indigenization process" (p. 698).

Long before the above definitions of indigenization were offered, Virgilio Enriquez, the forefather of IP in the Philippines, had been very much involved with the process since the early 1970s. This hands-on experience with IP led him to clarify two pathways of indigenization. The first path is *indigenization from without* (Enriquez, 1987, 1992) or *indigenization of the exogenous* (D. Sinha, 1997). Using the exogenous culture as the source, the flow of indigenization is inward, i.e., the indigenous culture is the target. The goal is to create or produce an indigenous version of the exogenous or imported materials, adapting the foreign material to the indigenous context. Typical examples are translation of Western theories, modification of psychological tests or other measures, and replication of Western studies. The second path of indigenization is *indigenization from within* or *cultural revalidation* (Enriquez, 1987, 1992) or *internal indigenization* (D. Sinha, 1997). Here, the source of concepts and methods is the indigenous culture. This path involves processes such as semantic elaboration, indigenous codification or recodification, and systematic explication of implied theoretical frameworks, to produce knowledge that reflects the indigenous experience and realities (Enriquez, 1987, 1992). This strategy of indigenization also pays attention to the application and use of the generated knowledge to benefit the indigenous. The outward flow indicates that there is every intention to apply or relate this outside the indigenous culture. The term 'indigenization' does not seem to fit this second pathway since, how do you indigenize something that is already indigenous? (Pe-Pua and Protacio-Marcelino, 2000); thus the term 'cultural revalidation' seems more appropriate.

India's J.B.P. Sinha offered five overlapping trends of indigenization: purist endogenous trend, endogenous indigenization, purist exogenous trend, exogenous indigenization, and integrative indigenization "in which Western and Indian concepts and methods were integrated to produce hybrid concepts and theories" (J.B.P. Sinha, 2003; also in Allwood and Berry, 2006: 256). Vohra (2004) argues for a combination of these trends to help and ensure the sustainability of the indigenization movement.

As borne out by the development of IP in various countries, there is no single path for developing IP. Each country has their particularities in terms of national history, policies, priorities, and positioning in the academic environment. These tend to influence the path taken by the majority and the minority of psychologists, as well as attitudes toward IP in general.

Cross-Indigenization

One of the end goals of IP is to contribute to universal psychology. In contrast to the cross-cultural approach of comparing cultures, Enriquez proposed 'cross-indigenization' as the strategy for consolidating various indigenization efforts. "In this model [cross-indigenization], the different cultures of the world are tapped as sources of cultural knowledge. The resulting pool may then be called 'cross-cultural knowledge.' More aptly, it is cross-indigenous knowledge…" (Enriquez, 1992: 86).

Development of IP in Various Parts of the World

As mentioned earlier, Allwood and Berry (2006) provided a good overview of the development of IP in various parts of the world. Notable among these countries in terms of advancement are those where 'indigenous' refers to the 'nonexogenous' such as the Philippines, India, and Taiwan; and those where 'indigenous' refers to the Indigenous peoples, such as New Zealand. These developments are outlined briefly below.

The development of IP in the Philippines is well documented (Pe-Pua and Protacio-Marcelino, 2000; Pe-Pua and Perfecto-Ramos, 2012; Yacat, 2013; Gastardo-Conaco, 2005). In fact, there is a wide recognition of the advanced development of IP in this country than any other (D. Sinha, 1997).

The indigenization movement in psychology also has a long history in Taiwan, spearheaded by Taiwanese psychologists Yang Kuo-Shu and Hwang Kwang Kuo (see Hwang, 2012 for a comprehensive history).

The IP movement in India has also been the subject of a number of writings (Sarawathi, in Allwood and Berry, 2006; J.B.P. Sinha, in Allwood and Berry, 2006; D. Sinha, 1997).

There are a number of similarities in the development of IP in the three countries. (1) All started IP development in the 1970s. The Philippines started in 1971 when its founder Virgilio Enriquez (1942–94) returned from the United States. Taiwan started in the late 1970s, with the founder Yang Kuo-Shu influenced by the development of IP in the Philippines. In the early 1970s, India's Durganand Sinha made a call "to make psychology relevant to the Indian context and to serve the needs of the Indian people" (Vohra, 2004). However, it was not until the 1980s that a clear articulation of IP was made. (2) There are recognized 'founding fathers' of IP in these countries: Enriquez (the Philippines), Yang (Taiwan), and D. Sinha (India). Both Enriquez and Yang were trained in the United States; both started thinking about IP even before they returned to their home countries. And after their return, they embarked on discussions with colleagues and planting the seeds for the development of IP. (3) All countries have professional organizations that are dedicated to the advancement of IP. (4) All countries have published large quantities of work on IP, mostly in the native languages. (5) The use of the native language in research and writing/publishing has been prevalent from the beginning of the IP movement in the Philippines and Taiwan. During the last 10 years, there have been pressures for these scholars to publish in English due to institutional pressure to publish in internationally refereed journals (in order to get academic promotion) and due to the need to promote IP internationally. (6) In all the three countries, indigenization from without has been the more popular path to indigenization.

Particular to the Philippines is the identification of four lines of filiations of psychology in the country: academic–scientific psychology, academic–philosophical psychology, ethnic psychology (which is the major basis of *Sikolohiyang Pilipino*), and the psychomedical system (Salazar, 1985).

Taiwan's IP development saw the determination "to refrain from uncritically or even blindly, applying American psychologists' concepts, theories, methods, and tools to the study of Chinese behaviour. Instead, they have based their studies on Chinese historical, cultural, social, and language traditions, especially the Confucian, Taoist, and Buddhist ones, and have sought to develop an indigenous Chinese psychology suitable for people in all the Chinese societies" (Yang, in Allwood and Berry, 2006: 251).

India's history of IP is no different from the Philippine and Taiwanese in terms of realizing the limitations of Western psychological theories and tools. But if the Philippines has its ethnic psychology as main basis, and Taiwan has its Confucian, Taoist, and Buddhist inspirations, Indian IP is "closely entwined with religion. Hinduism, which is described more as a way of life than as a religion, prescribes a code of conduct for human behaviour, recognizing the changing developmental tasks in different life stages" (Sarawathi, in Allwood and Berry, 2006: 255). Therefore, Indian IP draws on Hindu philosophy (Sarawathi, in Allwood and Berry, 2006: 255). In addition, it has a strong basis on folklore practices (D. Sinha, 1997).

The Philippines, Taiwan, and India are countries where indigenization has emerged in reaction to Western imported knowledge. The term 'indigenous' refers to the non-exogenous (aka non-Western), leading some scholars to suggest that the term 'national psychology' is more accurate than IP. Be that as it may, the use of the 'indigenous' perspective is what psychologists in these countries would hold on to in claiming that theirs is 'indigenous psychology.'

On the other hand, New Zealand, Canada, and Australia represent countries where the 'indigenous' in IP refers only to their original inhabitants. (We will discuss New Zealand only here since it has a clear history of indigenization in psychology.) Colonization of the Indigenous peoples in these countries is quite different from the three other countries discussed previously in the sense that the colonization process is ongoing as the Indigenous people continue to live side by side with their colonizers. As Sanson (2000) compares, in countries like the Philippines and India, "such a psychology [IP] would pertain to people of non-Western, largely non-industrialized nations, who have experienced colonization and domination by a Western power; but who nevertheless form the majority in their own country" (p. 13). In contrast, the Indigenous peoples in Australia and New Zealand form the minority of

the population, with the 'colonizer' background forming the majority. Furthermore, there are other cultural background groups in both countries, some of whom number more than the Indigenous groups. Thus, the struggle of indigenization of the discipline of psychology in these countries occurs hand in hand with the political struggle of the Indigenous peoples.

New Zealand's indigenization movement has focused on the relevance of psychology to the Indigenous people of the country, i.e., the Maori.

> Indigenous psychology in A/NZ [Aotearoa/New Zealand] has always been part of how Maori approach wellness, health, and being, stemming from a world-view that values balance, continuity, unity, and purpose … Perhaps it is best referred to by the Maori term *tikanga*, or customary practice – those behaviours, values, ways of doing things, and understanding actions that have always (sic) and will continue to be with us.
>
> Nikora et al., in Allwood and Berry, 2006: 254

Michelle Levy's (2007) PhD thesis *Indigenous Psychology in Aotearoa: Realising Maori Aspirations* provides a comprehensive account of the history of IP in A/NZ,

> "the current status of Maori development in psychology, the importance of the critical mass and the notion of collective responsibility … [It also] identifies 'reaching the point of irreversible change' as the next phase of indigenous psychology development in Aotearoa. This is the point at which indigenous psychology development becomes self-sustaining"
>
> (p. ii).

Just like the three countries previously discussed, psychology as a discipline in A/NZ was 'imported' from the West, having been introduced in 1874. Nikora and colleagues (in Allwood and Berry, 2006) pointed out that interest in Maori between the 1940s and the 1960s led to research that "was criticized for being 'on' Maori, rather than 'with' Maori (p. 254). It was not until around 1987 that psychologists became involved in the 'Maori development agenda,'" inspired and led by Mason Durie, a professor of Maori Studies, also a psychiatrist and a psychologist. Articulating *tikanga* in a clear and concise way, Durie's work has influenced the health and welfare sectors. The ongoing agenda for psychology is "to create psychologies to meet the needs of Maori people in a way that maintains a unique Maori heritage, and makes for a better collective Maori future… towards Maori self-determination… [This requires] the development of a critical mass of indigenous psychologists capable of developing robust *tikanga*-based psychological frameworks" (p. 255). In terms of action in promoting a Maori-centered psychology, Linda Nikora is regarded as the prime mover, with the help of the Maori and Psychology Research Unit based at the University of Waikato in Hamilton, New Zealand.

Achievements of IP

What do indigenous psychologists see as the achievements of IP? A common theme is decolonization. For example, IP in the Philippines started as a movement at a time when the country was rebelling against a dictatorial government, and rejecting 'imperialistic' influence from the West (aka America). Decolonization in psychology was about being critical of Western theories and methods, and discovering their 'own' psychology. The decolonization in Taiwan was also in terms of breaking away from Western psychology. Both countries felt the inadequacy of Western theories in explaining their realities. Decolonization was also an important component of IP history in A/NZ but this was focused on how psychology can help solve the impact of colonization on the well-being of the Maori people.

Another achievement of IP has been in redefining psychology or highlighting what is important as foci of the discipline. Enriquez (1975) took into account the study of emotions and experienced knowledge (*kalooban* and *kamalayan*), awareness of one's surroundings (*ulirat*), information and understanding (*isip*), habits and behavior (another meaning of *diwa*), and the soul (*kaluluwa*) which is the way to learn about people's conscience. Yang (1999) defined psychology as "an empirical science that investigates, from an individualistic-orientation and collectivist-orientation perspective, the contents, structure, mechanism, and processes of human mind and behavior conditioned by physical, biological, social, cultural, and historical characteristics at the intrapersonal, interpersonal, intragroup, and intergroup levels." The A/NZ perspective would focus on *tikanga* and related concepts as what constitute psychology.

Psychological testing is another area where both the Philippines and Taiwan made a contribution in terms of indigenization. This is not just the translation of foreign-made tests but starting with indigenous personality traits then moving to develop the tests.

Research methods is an area where IP in the Philippines has made a significant contribution. The advances in this area are discussed by Pe-Pua (2006). These have their humble beginnings in *pakapa-kapa*, introduced by Santiago (1977) and later defined by Torres (1982: 171) as "a suppositionless approach to social science investigations … characterized by groping, searching, and probing into an unsystematized mass of social data to obtain order, meaning and directions for research." The articulation of *pakapa-kapa* was significant, representing a turning point, paving the way to scrutinize research topics so that they could be more relevant to the needs of Filipinos. It dared the social scientists to question Western methods. "The resulting methods were considered indigenous – not imported nor invented, but natural or existing patterns of behaviour (not methods), discovered and developed as research methods" (Pe-Pua, 2006: 112). Aside from describing some of the indigenous methods that have emerged in the Philippine IP, Pe-Pua explained some guiding principles in undertaking psychological research the IP way. These are: (1) how the quality of research data is affected by the level of social interaction between researcher and participants; (2) the importance of treating participants as equal; (3) valuing the welfare of participants more than just getting data from them; (4) choosing methods on the basis of appropriateness, and adapting these to existing norms; and (5) the language of the participants should be the language of research (Pe-Pua, 2006).

Indigenous Theorizing

IP has made some inroads in identifying and developing indigenous concepts and theories – not necessarily to be unique to one culture only, but unique in the sense of not having been tapped or articulated as culturally sensitive in mainstream psychology. Some examples are given below.

Enriquez's book *From Colonial to Liberation Psychology* (1992) provides a good overview of the early development and philosophy of *Sikolohiyang Pilipino* (indigenous Filipino psychology). Enriquez discovered *kapwa* as a core Filipino indigenous concept which turned out to be the antithesis of the Western individual-centered 'self.' The English 'others' is used in opposition to the self, implying the separation of the self as a separate identity. In contrast, *kapwa* is a recognition of shared identity, an inner self shared with others; the unity of 'self' and 'others'; or fellow human beings (Enriquez, 1978, 1994). In Filipino psychology, *ako/sarili* (I/self) is associated with selfishness or egocentricism. There are words in the Filipino language for 'I' (*ako*) and 'others' (*ibang tao*) but both are included in *kapwa* psychology, so much so that a Filipino would say, "*Hindi ako iba sa aking kapwa* (I am no different from others)" (Enriquez, 1994). Several studies and writings have focused on *kapwa*, including its place in indigenous research approaches (see Pe-Pua, 2006 for a summary), and *kapwa* as value and social interaction (Enriquez, 1978, 1994). The concept of *kapwa* reflects the flexibility by which Filipinos navigate the domains of inclusion–exclusion or membership/non-membership. These domains are relevant to Filipinos, but in a more flexible way. While Filipinos make a distinction between the *ibang-tao* ('not one of us') and the *hindi-ibang-tao* ('one of us'), both categories are accommodated in the concept of *kapwa*.

The Taiwanese Yang Kuo-Shu's (1995) theory of Chinese social orientation is quite advanced and has potential application to other cultures. This is a theory of Chinese psychological functioning centering on the key concept of social orientation as a comprehensive system as well as a synthetic pattern of Chinese dispositional characteristics. Yang (1999: 194) defined social orientation as "a person's tendency to establish and maintain a harmonious relationship with, and merge into, the surroundings so that collective and relational goals can be effectively achieved." Yang's theory points to four closely related orientations: familistic orientation, other orientation, relationship orientation, and authoritarian orientation. The relationship orientation is particularly elaborate, consisting of three compartmentalized categories of relationship: *jiaren* (family members); *shuren* ('cooked' persons: relatives outside the family, people in the same village, neighbors, friends, colleagues, and classmates); and *shengren* ('raw' persons like strangers). These categories require distinct modes of interaction in accordance with different principles: *jiaren* (*zeren* or responsibility); *shuren* (*renqing* or interpersonal favor and affect); *shengren* (*lihai* or an eye on possible gains and losses) (Yang, 1999).

Another Taiwanese psychologist Hwang (2012) has been advocating for culture-inclusive theories in psychology following Shweder's (Shweder et al., 1998) principle of 'one mind, many mentalities.' He has urged the IP movement to have as its mission "to initiate a scientific revolution by constructing a series of theories on the presumption of relationalism in replacing Western theories of individualism, so as to help people of non-Western countries solve the various problems they encounter in their daily lives" (Hwang, 2013: 717). He integrated the various theoretical contributions of Chinese IP, as well as the history and philosophy of Chinese IP in his book *Foundations of Chinese Psychology: Confucian Social Relations* (Hwang, 2012).

Hwang's theoretical model of face and favor is a major contribution in this direction of indigenous theorizing. This is basically a theory in interpersonal relationship that is related to four key indigenous concepts: *guanxi* (relationship), *renqing* (favor), *mianzi* (face), and *bao* (reciprocation) (Hwang, 2012). Hwang identified four kinds of interpersonal ties: expressive ties, mixed ties, instrumental ties, and vertical relationship. He then related them to Fiske's (1991) model of elementary forms of social behavior. He then illustrated how certain forms of social behavior are given more credence depending on the orientation of the particular society on the individualism ideal (Hwang, 2013).

There are more examples from the Philippines and Taiwan where IP has developed a quite advanced history. Enriquez's theory of *kapwa*, Yang's theory of social orientation, and Hwang's theory of face and favor present an opportunity for developing a cross-indigenous (it will be premature to speculate 'universal' at this point) theory of the social self. There are a number of similarities across the three theories, which will be the subject of future writings.

The relational orientation was also prominent in Indian indigenous theorizing. Instead of the duality of man and society in Western conceptualization, the Indian perspective values 'man-society' where the two cannot be separated (D. Sinha, 1981). "The individual's identity is conceived not so much in terms of his/her personal qualities and achievements, but in the context of his/her family, caste, place, institutions, and a whole web of interpersonal roles and relationships. It is in this perspective that social behavior is analyzed and interpreted" (D. Sinha, 1997: 151). This relational model is also congruent with Indian healing practices (Kakar, 1984). Incidentally, several indigenous Indian concepts and practices have permeated and have been embraced by Western psychotherapy, including *Yoga*, *Ayurveda*, and so on. These are clear contributions to the discipline of psychology.

There is a Maori concept that comes close to relationalism – *whanangatanga*, meaning relationship, relatedness – that is quite prominent in A/NZ IP development.

Japanese IP is also a source of indigenous theorizing that has potential international application. One such concept that has gained international attention is *amae*, which is defined by Yamaguchi (1999, cited in Yamaguchi and Ariizumi, 2006) as

> …presumed acceptance of one's inappropriate behavior or request. In close relationships, one is able to presume that one's inappropriate behavior or request will be accepted due to the positive or at least non-negative attitude of one's counterpart. This definition of *amae* implies that two components, the inappropriate behavior or request and the presumption of acceptance, are involved in *amae* episodes.
>
> p. 165

There are indeed several developments in indigenous theorizing that could be pulled together through systematic research in order to illustrate the potential contribution to psychological theory in different fields of the discipline.

Issues and Debates on IP

Psychologists undertaking IP work face a number of challenges and issues. One challenge is related to the language of research and publication. In countries where the first language is not English, most of the publications on IP work are in the local languages, mainly due to the philosophy behind IP that they uphold, i.e., IP should be developed and is best understood and articulated using the local language. In fact, in India, one of the reasons identified for the slow progress in developing IP is the reduced usage of the local languages, which is explained in terms of the dilemma of diversity in languages, religions, and grouping in the country. In some countries, the lack of publication in English, which would make IP more accessible internationally, is due to their lack of English proficiency. A subtle reason also is the attitude held by some psychologists that spreading IP knowledge internationally is not a priority; what is important is that the national development benefits from IP knowledge. Another obstacle to publishing, in general, is the heavy teaching load in many universities and the lack of support (or pressure) to conduct research and have this recognized as part of their academic workload.

Indigenous theorizing is an important undertaking if IP is to be taken seriously by the wider international community of psychologists. Any theorizing, however, is neither a simple nor a straightforward process. There is even a question of whether indigenous theories are useful, i.e., are these just confined to the indigenous cultures or do they have potential to be universal? Stevenson (2000) speculated on 'indigenous theories' failure to flourish,' offering the following reasons: (1) lack of resources for research to advance theorizing; (2) the disciplinal bias for topics that are interesting to a more universal audience; (3) difficulty with linguistic translation; (4) the use of a mere translated version of Western instruments that may not be relevant to the indigenous population; and (5) 'newness of the considerations' – there are simply not enough studies done.

The reality is that there is already a wealth of indigenous concepts and theories out there that are in various stages of development. A more systematic and well-resourced stocktaking is required to bring these out. The body of knowledge needs to be synthesized, and future directions for research are to be guided by this synthesis.

Cross-indigenization would seem to provide a good process for extending the applicability or relevance of indigenous concepts and theories to a more international context. For example, some Japanese psychologists provide a good example of cross-indigenization without necessarily being aware of it. When they identify a 'Japanese' (they do not readily use the word 'indigenous') concept, they try to understand it from the indigenous perspective, relate it immediately to the Western concepts closest to it, and try to collect empirical data, not only with Japanese subjects, but also with non-Japanese subjects. In many cases, part of the comparison is with Western subjects.

Cross-indigenization is a pathway to discovering universals, if there is indeed such a thing. For example, Yamaguchi and Ariizumi (2006) speculate, as a result of an initial investigation of the Japanese concept of *amae* across three cultural groups, that *amae* could be an etic construct. At the same time that researchers of IP need to be supported in contributing to universal psychology, the wider scholarly community also needed more acceptance and valuing of IP. Developing IP and cross-indigenization help us move away from 'intellectual prejudice,' 'entrenched intellectual habits,' and 'cultural myopia.' Cross-indigenization provides a balance of flow of knowledge between East and West. Not only that, the flow of knowledge within the East is also important. Cross-indigenization also helps us bridge the gap between 'emotional overreactions' and blind assumption that "scientific psychology is a monopoly of the West" (Enriquez, 1992).

In terms of future directions of IP, Church and Katigbak (2002) offered seven pressing needs in relation to Philippine IP that could very well apply to other IPs as well. These are:

> "the formulation of indigenous theory; objective consideration informed by empirical data; continuing development and validation of indigenous measures; systematic investigation of the comparative and convergent validity of various indigenous and imported research methods; institutional/structural improvements leading to growth and stability of the indigenous research culture; maintenance of an appropriate balance between the pursuit of an independent psychology and the avoidance of insularity; and eventually, increased efforts to relate cross-indigenous approach toward a universal psychology"
>
> (p. 141).

By way of concluding, it is important to highlight that IP has been the subject of a number of edited volumes that are inclusive of different countries. The earliest of these was Kim and Berry's (1993) book *Indigenous Psychologies: Research and Experience in Cultural Context* (Sage). A more recent one, Kim et al.'s (2006) volume, *Indigenous and Cultural Psychology: Understanding People in Context* (Springer) was the result of an intensive seminar-workshop in Taiwan that explored the latest developments of the time. This book was then reviewed by a number of authors, with the reviews published in a special issue of the journal *Pastoral Psychology* (volume 56, 2007), a Springer journal. A few journals have also promoted discussion and publication on IP. For example, volume 3, issue 3 (2000) of the *Asian Journal of Social Psychology* provoked a healthy exchange in clarifying the distinctions between cultural, cross-cultural, and indigenous psychology. Another issue of the journal, volume 8, issue 1 (2005) was dedicated to "responses to the epistemological challenges to indigenous psychologies." The *International Journal of Psychology* also devoted a "Special issue on the indigenous psychologies" (volume 41, issue 4, 2006).

Abstract

Indigenous communities and nation-states understand indigenous rights in different and contested ways. However, as indigenous people increasingly appeal to the international community and international law to secure their rights against encroaching state and private interests, the term 'indigenous rights' has come to refer to a specific set of rights codified within the corpus of international law or set forth as international standards. This article discusses the historical origins and development of the contemporary indigenous rights regime through instruments of international law and policy.

Introduction

Indigenous communities and nation-states understand indigenous rights in different and contested ways. However, as indigenous people increasingly appeal to the international community and international law to secure their rights against encroaching state and private interests, the term 'indigenous rights' has come to refer to a specific set of rights codified within the corpus of international law or set forth as international standards. This article discusses the historical origins and development of the contemporary indigenous rights regime through instruments of international law and policy.

There is no universal definition of what it means to be 'indigenous.' The term 'indigenous' did not gain significance until after the onset of European exploration, when settler societies needed a way to collectively identify the hundreds of culturally diverse Native groups that typically self-identified by a name of their own language (Bruyneel, 2007: p. ix). Today a shared global identity around being indigenous is common. Within the indigenous rights framework, "[t]he rubric of indigenous peoples includes the diverse Indian and aboriginal societies of the Western Hemisphere, the Inuit and Aleut of the Arctic, the aboriginal peoples of Australia, the Maori of Aotearoa (New Zealand), Native Hawaiians and other Pacific Islanders, the Sami of the European far North, and at least many of the tribal or culturally distinctive nondominant peoples of Asia and Africa" (Anaya, 2009: p. 1). This list is not exhaustive of the rich multiplicity of cultures and lifeways of the more than 370 million indigenous people living throughout the world (Permanent Forum Factsheet). The United Nations (UN) describes indigenous people as sharing the characteristics of self-identification, strong communal ties tracing to precolonial and presettler Indigenous groups, strong cultural ties with traditional lands, and as practicing distinct linguistic, social, political, economic, and religious ways that differ from the dominant society (Permanent Forum Factsheet).

This article provides a general introduction to indigenous rights. First, it outlines the historical development of indigenous rights as a subject of international law. Second, it discusses the treatment of indigenous rights in binding international treaties and in international jurisprudence. Third, it discusses the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP), as well as other legal sources of indigenous rights. Finally, it concludes by highlighting some of the critical debates in indigenous rights scholarship and practice.

Historical Development of Indigenous Rights

Colonialism and the Doctrine of Discovery

Indigenous peoples have a long history of internal, intertribal, and even international legal traditions. Some early encounters between Native peoples and Europeans were relatively peaceful, reflecting indigenous diplomacy and giving rise to mutually beneficial alliances for trade and political purposes (Williams, 1990). Others were not. The origin of indigenous rights as part of the state-based international legal order can be traced to the legal and political systems that governed European exploration, conquest, and colonization of the Western hemisphere. Papal law, dating as early as the eleventh century as the justification for the Holy Wars (Crusades) in Europe, granted the Church universal jurisdiction over all non-Christian lands and encouraged exploration and religious conversion of Native peoples (Miller, 2005). Violence between indigenous peoples and Europeans followed, along with enslavement, conquest, and devastation of Native peoples.

In the fifteenth century, European legal theorists began questioning the moral and legal right for Church-backed monarchs to assume control over indigenous lands. Natural law principles postulating moral and ethical ideals above the interests of the monarch suggested that indigenous peoples, like the rest of humanity, possess an innate set of rights. Spanish legal theorists and Dominican clerics Bartolmé de las Casas (1474–1566) and Francisco de Victoria (1486–1547) challenged the callous treatment and enslavement of indigenous peoples by affirming that indigenous peoples were indeed human beings, and thus entitled to certain rights possessed by all humans, such as control over property (Anaya, 2004a, b).

Although natural law theorists challenged the legality of conquest by discovery alone, they also argued that conquest could be justified if for the benefit of the Native peoples, severely limiting the scope of indigenous rights at its inception. De Victoria wrote that Native peoples are "unfit to found or administer

a lawful State up to the standard required by human and civil claims … therefore, be maintained that in their own interests the sovereigns … might undertake the administration of their country … so long as this was clearly for their own benefit" (de Victoria, 1557: p. 160). These ideas were incorporated into the articulation and application of the Doctrine of Discovery, which explicitly governed relations among competing European nations, and marked the first instantiation of indigenous rights as an issue of international law. The Doctrine of Discovery granted the first Christian European power to arrive on foreign soil the exclusive right to purchase or otherwise conquer Native lands against all other Christian European nations. "When European countries, and later the United States, set out to exploit new lands in the fifteenth through twentieth centuries, they justified their claims over these territories and over indigenous peoples with the Doctrine" (Miller, 2011: p. 330).

The Formation of the Modern International Legal System

Indigenous rights receded from the international arena and became part of the domestic affairs of states in the late seventeenth century. The 1648 Treaty of Westphalia ushered in a new era of international law defined by the Law of Nations. Emmerich de Vattel (1714–69) wrote that individual nation-states are equal, independent, and hold their own rights. Vattel's premise was solidified in the late nineteenth and early twentieth century by legal positivists who argued that international law could only govern state rights, and that the principle of mutual sovereignty shielded the internal affairs of individual states from international interference without consent. Post-Westphalian principles of sovereignty shielded domestic treatment of indigenous rights from international scrutiny, and indigenous peoples became subject to the unmitigated will of states to eliminate Native cultures, take Native lands, and strip Native peoples of political mobility (Anaya, 2009).

Many of the emerging domestic indigenous rights regimes incorporated the Doctrine of Discovery. In the United States, the Doctrine was famously invoked in 1823 by Supreme Court Justice John Marshall in the decision of *Johnson v. McIntosh* where the Court held: "[D]iscovery gave title to the government by whose subjects, or by whose authority, it was made against all other European governments, which title might be consummated by possession" (Johnson v. McIntosh, 1823: p. 573). In Marshall's formulation, the Doctrine of Discovery meant that the 'courts of the conqueror' would only recognize property transfers from indigenous nations to the national government, and not to private citizens. However, the Doctrine also recognized that indigenous peoples retained usufructuary, or use rights by permitting the continued use and occupation of traditional lands even after discovery, unless or until the United States chose to extinguish aboriginal title by purchase or conquest. This system of ownership established by the Doctrine of Discovery formed the foundation of the trustee relationship and the backdrop for domestic indigenous rights regimes in the United States, Australia, New Zealand, and Canada that still exist today (Miller and Ruru, 2008; Williams, 2012).

Although the Doctrine of Discovery and positivist developments in international law weakened the power of indigenous peoples internationally, the sovereign status of indigenous peoples remains viable largely due to the simultaneous practice of treaty making. Beginning in the early 1600s and continuing through as late as the early 1900s, English, Dutch, Spanish, and French colonists made treaties with tribal governments, recognizing the sovereign prerogative of indigenous peoples to make and enact binding instruments of international law that established conditions of peace and secured indigenous rights to property, governance, and natural resource use to name a few (Cohen and Newton, 2009: §1.01). Today, treaties continue to form the basis for domestic indigenous rights regimes in the United States, Canada, New Zealand, and Australia (Williams, 1999).

The horrors of World War I brought indigenous rights back into the international spotlight as part of the nascent human rights movement and the establishment of the League of Nations in 1919. Despite the inability of nonstates to participate in the League of Nations, indigenous peoples persisted in attempting to lobby for their rights. For example, the representative of the Six Nations of the Grand River and chief of the Younger Bear Clan of the Cayuga Nation Levi General Deskaheh lived in Geneva from September of 1923 until the end of 1924, while attempting to gain a hearing at the League of Nations. Deskaheh sought to resolve a dispute with the Canadian government over the 1876 Indian Act, which forced tribal peoples to form elected band councils for the purpose of eliminating traditional indigenous governments. Deskaheh argued that he had a right to a hearing because he represented a sovereign state, based in part on the Haldiman Treaty of 1784 in which King George III reserved the Grand River territory to the Iroquois who fought for the British during the American Revolution. While Deskeheh never obtained an official hearing at the League of Nations, he garnered support from at least six other nations and renewed the presence of indigenous peoples in international law (Niezen, 2003).

The League of Nations dissolved by the late 1930s but gave rise to the establishment of the United Nations (UN) in 1945 after the human rights violations of WWII. The UN provided a new forum for staging indigenous rights as part of the broader human rights movement in international law. Like the League of Nations, the UN is based on the founding principle of state sovereignty. However, in the aftershock of Nazi-genocide, the UN recognized the need to protect all human rights even if that meant that sovereignty could no longer be an absolute shield from international intervention in domestic affairs. This shift demonstrated the resurgence of principles of natural law in international law by championing the 'equal rights and self-determination of all peoples' including respect for fundamental freedoms regardless of race, sex, language, or religion (UN Charter, 1945: art. 2). The rights introduced in the UN Charter were articulated in 1948 with the adoption of the Universal Declaration of Human Rights, which were later codified in a series of binding international treaties and covenants setting the framework for contemporary indigenous rights as a part of the broader human rights movement (Niezen, 2003).

Binding International Law and Treaty Jurisprudence

International Treaties

In the mid-to-late twentieth century, the continued presence of indigenous peoples in international forums, coupled with the

recognition of individual and group rights as distinct from those of states, inspired emergence of a series of international organizations and binding covenants that form the basis for indigenous rights today (Henderson, 2008). The major instruments providing the backdrop for indigenous rights are the International Covenant on Economic, Social, and Cultural Rights (ICESCR) and International Covenant on Civil and Political Rights (ICCPR) passed at UN General Assembly in 1966 and the Convention on the Elimination of All Forms of Racial Discrimination (Convention) held in 1969. Although none of these instruments explicitly mentions indigenous people, they each establish a set of substantive rights as well as monitoring bodies to investigate state conduct with respect to rights guaranteed to all minority peoples. The 1989 International Labour Organization (ILO) Treaty No. 169 Concerning Indigenous and Tribal Peoples in Independent Countries (ILO 169) was the first treaty to explicitly mention indigenous rights. The primary monitoring bodies established by these treaties are the Human Rights Committee, now called the Human Rights Council (HRC), of the ICCPR and the Committee on the Elimination of Racial Discrimination (CERD) of the Convention. States were required to specifically adopt the monitoring bodies as optional protocols.

The treaties most frequently cited in indigenous rights cases are the ICCPR and ILO 169. The ICCPR provides the backdrop for indigenous rights by establishing the rights of 'peoples' in Article 1 and the rights of 'minorities' in Article 27. Article 1 of the ICCPR, which is identical to article 1 of the ICESCR, granted all peoples the right to self-determination. It holds that "[a]ll peoples have the right of self-determination … [and that] … By virtue of that right they freely determine their political status and freely pursue their economic, social and cultural development" (ICESCR, 1966: art. 1; ICESCR, 1966: art. 1). Indigenous peoples often insist that they fall under article 1 and that their right to self-determination is equal to that of all peoples and that self-determination is the basis for a myriad of correlative rights. "Self-determination is not separate from other human rights norms; rather, self-determination is a configurative principle or framework complemented by the more specific human rights norms that in their totality enjoin the governing institutional order" (Anaya, 2004b: p. 99). In other words, the right to self-determination informs all other indigenous rights.

The substantive content of the right to self-determination is contested as it pertains to indigenous peoples. Traditional interpretations argue that the right to self-determination embodies a twofold right to both 'internal' and 'external' self-determination (Anaya, 2004b). Internal self-determination refers to self-governance, or the right to practice independent political, social, and cultural rule as distinctive groups within the colonizing government. External self-determination refers to the ability to participate as a distinct sovereign amongst other governments. The question of whether indigenous peoples enjoy the right to both internal and external self-determination has inspired debate. Some settler states fear that recognizing a right to external self-determination grants a right of secession thereby threatening the fundamental international law tenet of states' territorial sovereignty (Morgan, 2004; Cassese, 1995; Coulter, 2010). Yet, from another perspective, indigenous peoples often articulate a vision of self-determination in which they have the rights to govern their members and territories, to be recognized and represented as indigenous peoples in state political processes, and to be protected from the expansion of colonist regimes over lands, political systems, and cultures (Anaya, 2009).

Whereas article 1 protects the right to internal self-determination for 'peoples,' article 27 of the ICCPR protects the rights of 'minorities' to practice their unique cultures within the political fabric of the state. Article 27 holds that "States in which ethnic, religious, or linguistic minorities exist, persons belonging to these minorities shall not be denied the right, in community with the other members of their group, to enjoy their own culture, to profess and practice their own religion, or to use their own language" (ICCPR, 1966: art. 27). Although the ICCPR does not specifically mention indigenous people, article 27 has been interpreted to protect the rights of indigenous people as minorities, to exercise their distinct cultural traditions as a group, free from discrimination by the state (see, e.g., Ominayak, 1990 *infra*). Additionally, the ICCPR and ICESCR affirm a series of human rights necessary for the equal and dignified treatment of all peoples. For example, the ICCPR affirms the right to life (ICCPR, 1966: art. 6), the right to liberty, security, and freedom of movement (ICCPR, 1966: arts. 9–12), the right to not be enslaved or subject to compulsory labor (ICCPR, 1966: art. 7), the right to equal protection before the law (ICCPR, 1966: art. 16), and the right to freedom of thought, opinion, and religion (ICCPR, 1966: arts. 18–19). The ICESCR affirms the right to work, unionize, and strike (ICESCR, 1966: arts. 6–8), the right to education (ICESCR, 1966: arts. 13–14), and the right to culture (ICESCR, 1966: art. 15).

The ICCPR, ICESCR, and the Convention inspired the UN to declare the Decade for Action to Combat Racism and Racial Discrimination in 1980, which premised the formation of the Working Group on Indigenous Populations (Working Group) in 1982. The Working Group was established by the UN Economic and Social Council for indigenous leaders and advocates from around the world to participate in yearly forums to voice the challenges facing Native peoples both as part of, and distinct from, the challenges of all minority peoples (Charters and Stavenhagen, 2009). This renewed presence of indigenous peoples at the UN resulted in the first major treaty to incorporate indigenous participation in the formation of indigenous rights.

In 1989, the ILO set important precedent for the promulgation of indigenous rights when it passed ILO 169 treaty as a revision of ILO No. 107 signed in 1975. ILO No. 107 initially addressed indigenous working conditions but failed to address issues of culture or self-determination and had a distinct assimilationist flavor. ILO 169 was the first major treaty to expressly denounce past policy in reference to indigenous rights and considers that "developments in the situation of indigenous and tribal peoples in all regions of the world, have made it appropriate to adopt new international standards on the subject with a view to removing the assimilationist orientation of the earlier standards…" (ILO 169, 1989, preamble). Today, 22 countries have ratified ILO 169, including most Central and South American countries, but excluding Canada, the United States, and most African nations. The basic philosophy of ILO 169 is to establish respect for indigenous

cultures and lifeways through the process of consultation in national decisions that affect them (Anaya, 2009).

For example, article 2 provides that governments "have the responsibility for developing, with the participation of the peoples concerned, coordinated and systematic action to protect the rights of these peoples … promoting the full realization of the social, economic, and cultural rights of these peoples with respect for their social and cultural identity, their customs and traditions and their institutions" (ILO 169, 1989: art. 2). Read with article 6, which mandates that consultation be carried out "in good faith … with the objective of achieving agreement or consent…", ILO 169 affirms the right to meaningful consultation with national governments over decisions that would affect the ability of indigenous peoples and individuals to maintain distinct cultural systems and governance (ILO 169, 1989: art. 6). Although ILO 169 clearly orders some form of consultation, and even consent in some articles, the mechanisms and extent of consultation with indigenous peoples remains largely undefined in international treaties. No state understands 'consultation with the objective of consent' to grant veto power to indigenous peoples, however, and the degree of consultation practiced by states varies.

Perhaps the most important and contentious right secured to indigenous peoples in ILO 169 is the right to land, as developed in articles 13–19. Article 14 provides that indigenous peoples retain "the rights of ownership and possession of the peoples concerned over the lands which they traditionally occupy … [and that] … [g]overnments shall take steps as necessary to identify the lands which the peoples concerned traditionally occupy, and to guarantee effective protection of their rights of ownership and possession" (ILO 169, 1989: art. 14). This article asserts that indigenous peoples have existing rights to their traditional territories, and mandates that settler states recognize and protect those rights against encroaching interests at least as well as for properties owned by non-Native citizens. Whether the right to own and occupy traditional lands extends to the natural resources above and below the surface right is unclear. At the very least, article 15 specifically secures the right to consultation over natural resource development on traditional territories. Article 15 provides "[t]he rights of the peoples concerned to the natural resources pertaining to their lands shall be specially safeguarded. … In cases in which the State retains the ownership of mineral or subsurface resources or rights to other resources pertaining to lands, governments shall establish or maintain procedures through which they shall consult these peoples…" (ILO 169, 1989: art. 15). The indigenous right to consultation over the use of natural resources on traditional lands is echoed in the right against removal or relocation. Article 16 provides that if indigenous peoples must be removed from their land, it shall only take place with "their free and informed consent … [and] … [w]here their consent cannot be obtained, such relocation shall take place only following appropriate procedures…" and with compensation in the form of equivalent lands or monies (ILO 169, 1989: art. 16).

Because of the unique relationship indigenous people maintain with their traditional territories, violations of the right to land lead to violations of many other rights affirmed in ILO 169 such as labor rights that secure equal treatment of all citizens in terms of pay and employment conditions, access to vocational training, as well as the right to health and education (ILO 169, 1989: arts. 20–32). Some scholars have been critical of how ILO 169 and other treaties elevate the relationship of indigenous peoples to their land as something that is culturally distinct and separable from broader modern society, arguing that this approach runs the risk of limiting indigenous land claims and essentializing indigenous cultures (Engle, 2009). The contentious nature of the indigenous right to land and the ambiguity of the right to consultation have spurred the majority of disputes over indigenous rights.

International Treaty Jurisprudence

Disputes over indigenous rights are reviewed and decided by the treaty monitoring bodies, especially the HRC, and increasingly by international tribunals. The initial disputes over indigenous rights proceeded under the HRC pursuant to the jurisdiction of the ICCPR and its optional protocol. In the majority of these cases, indigenous peoples challenged state or private encroachment on indigenous lands and resources under the article 1 right to self-determination and the article 27 minority rights provision, which gave rise to violations of other articles (see, e.g., *Sandra Lovelace v. Canada*, No. 24/1977, U.N. Doc. CCPR/C/OP/1 (1984), *Kitok vs. Sweden*, No. 40/1988 U.N. Doc. CCPR/A/43/40 (1988); *Bernard Ominayak, Chief of the Lubicon Lake Band vs. Canada*, No. 167/1984, U.N. Doc. CCPR/C/38/D/167/1984 (1990); *Lansman et al. vs. Finland*, No. 511/1992, U.N. Doc. CCPR/C/52/D/511/1992 (1999); *Francis Hopu and Tepoaitu Bessert vs. France*, No. 549/1993, U.N. Doc. CCPR/C/60/D/1993/Rev.1 (1997); *Mikmaq Tribal Society vs. Canada*, No. 205/1986, U.N. Doc. CCPR/C/39/D/205/1986 (1990); *Apirana Mahuika et al. v. New Zealand*, No. 547/1993, U.N. Doc. CCPR/C/70/D/547/1993 (2000)).

For example, in *Chief Bernard Ominayak and the Lubicon Lake Band vs. Canada*, the Lubicon Lake Band of Cree Indians alleged that the Government of Canada violated the Tribe's article 1 "right to self-determination and by virtue of that right to determine freely its political status and pursue its economic, social and cultural development, as well as the right to dispose freely of its natural wealth and resources and not to be deprived of its own means of subsistence," when it allowed the provincial government to lease the Tribe's traditional lands for oil, gas, and timber development (Ominayak, 1990: paras. 2.1 and 2.3). These developments precluded the Lubicon Band from practicing traditional ways of subsistence and degraded the environment to such an extent that they risked survival as a Tribe altogether. The HRC found that "the author, as an individual, could not claim under the Optional Protocol to be a victim of a violation of the right to self-determination … which deals with the rights conferred upon peoples, as such" (Ominayak, 1990: para. 13.3). However, the HRC did rule that the Canadian government violated a series of other articles that could be covered under a violation of article 27. It wrote, "[h]istorical inequities, to which the State party refers, and certain more recent developments threaten the way of life and culture of the Lubicon Lake Band, and constitute a violation of article 27 so long as they continue" (Ominayak, 1990: para. 33). This decision confirmed the indigenous right to

culture while recognizing the connection of subsistence practices on traditional lands to indigenous survival.

Contrastingly, in *Apirana Mahuika et al. v. New Zealand*, the HRC declined to find that the government of New Zealand violated article 27 when it entered into the 1992 Settlement Act (Settlement Act) with a group of Maori people to settle all fisheries disputes between the Maori and the state through a quota system. The case was brought by a second group of Maori people who claimed that the contracting group did not represent them, that they were not adequately informed nor did they participate in the negotiation, and therefore that New Zealand had violated article 27 and a series of associated rights enumerated in articles 6 to 27 which it restricted Maori fishing rights under the Settlement Act. The HRC reasoned that "the acceptability of measures that affect or interfere with the culturally significant economic activities of a minority depends on whether the members of the minority in question have had the opportunity to participate in the decision-making process in relation to these measures and whether they will continue to benefit from their traditional economy," and ruled that New Zealand did properly engage the Maori people negotiation of the Settlement Act (Apirana, 2000: para. 9.5). It cautioned, however, that New Zealand is still bound by article 27, and that "measures affecting the economic activities of Maori must be carried out in a way that the authors continue to enjoy their culture, and profess and practice their religion in a community with other members of their group" (Apirana, 2000: para. 9.9).

Some scholars and advocates argue that the HRC has proven insufficiently sympathetic to indigenous causes, criticizing the HRC's apparent reluctance to treat indigenous peoples as 'peoples' under article 1 and its tendency to find article 27 violations in only the most extreme situations such as "forcible relocation, severe environmental degradation and denial of access to subsistence areas and areas of cultural and religious significance" (MacKay, 2001: p. 13). From another perspective, however, the HRC has laid important groundwork for treating indigenous peoples as eligible for human rights under the ICCPR (Anaya, 2009).

Regional Treaty Jurisprudence

The Organization of American States (OAS) is a regional human rights regime, consisting of the United States, Canada, Mexico, the Caribbean, and all countries in Central and South America, which has adopted a series of human rights instruments that affirm norms similar to those in the UN treaties and declarations. Most notably in the indigenous context, the OAS adopted the American Declaration of the Rights and Duties of Man in 1948 and the American Convention on Human Rights (American Convention), which came into force in 1978. The American Convention has subsequently been supplemented with various additional protocols including the Additional Protocol to the American Convention on Human Rights in the Area of Economic, Social, and Cultural Rights (Protocol of San Salvador); Protocol to the American Convention on Human Rights to Abolish the Death Penalty; Inter-American Convention to Prevent and Punish Torture; Inter-American Convention on Forced Disappearance of Persons; Inter-American Convention on the Prevention, Punishment, and Eradication of Violence Against Women (Convention of Belém do Pará); and the Inter-American Convention on the Elimination of Discrimination Against Persons with Disabilities, to name a few. The OAS is also working on a draft of the proposed American Declaration on the Rights of Indigenous Peoples. Like the UN instruments, the American Convention also establishes monitoring bodies for treaty compliance by ratifying states. The American Commission on Human Rights (American Commission) initially reviews alleged disputes, and either resolves or recommends those disputes to be decided by the Inter-American Court on Human Rights (Inter-American Court). Notably, the United States has not submitted to the jurisdiction of the Inter-American Court.

In 2001 the Inter-American Court set international precedent when it upheld the indigenous right to property in *The Case of the Mayagna (Sumo) Awas Tingni Community v. Nicaragua*. In this case, the Nicaraguan government granted a logging concession to a foreign company on the traditional lands of the Indigenous Awas Tingni community. The Awas Tingi challenged the Nicaraguan government in the Inter-American Court alleging that it had violated the community's right to property and other related human rights, as well as the right to judicial protection. The Inter-American Court cited to ILO 169, the American Convention, and other Inter-American instruments of international law including the draft of the United Nations Declaration on the Rights of Indigenous People (discussed *infra*) to rule in favor of the Awas Tingni. It found that Nicaragua violated the Awas Tingni right to property and violated the community's right to judicial protection, and mandated that Nicaragua pay monetary damages. Additionally, the Inter-American Court found that "the State must adopt in its domestic law … the legislative, administrative, and any other measures necessary to create an effective mechanism for delimitation, demarcation, and titling of the property of Indigenous communities, in accordance with their customary law, values, customs and mores" (Awas Tingni, 2001: para. 143).

The ruling in *Awas Tingni* ushered in a new way of interpreting indigenous rights by considering them in light of community-specific traditions and group rights. Most notably, the Inter-American Court recognized a communal property right as derived from traditional tenure practices as equivalent to the individual title based system recognized by the state. In finding that the human right to property "embraces the communal property regimes of indigenous peoples as defined by their own customs and traditions," the Inter-American Court adopted an "evolutionary method of interpretation, taking into account normative international developments both within and outside the Inter-American system" (Anaya and Grossman, 2002: p. 12). Following *Awas Tingni*, the American Commission and the Inter-American Court have affirmed the group indigenous right to property and corollary rights such as the right to life and cultural integrity in a growing number of cases favoring indigenous plaintiffs (see, e.g., *Mary and Carrie Dann vs. United States*, Inter-Am. Ct. Hum. Rts. Report No. 75/02, 27 Dec. 2002, OEA/Ser.L/V/II.117 Doc. 5 rev. 1 (2003), the case *Maya Indigenous Communities vs. Belize*, Inter-Am. Ct. Hum. Rts. Report No. 40/04, Oct. 12, 2004; *Yaka Axa Indigenous Community vs. Paraguay*, Inter-Am. Ct. Hum. Rts. (Ser. C) No. 125 (17 June 2005); *Miowana Community vs. Suriname*,

Inter-Am. Ct. Hum. Rts. (Ser. C) No. 145 (8 Feb. 2006); *Sawhoyamaxa Indigenous Community vs. Paraguay*, Inter-Am. Ct. Hum. Rts. (Ser. C) No. 146 (29 Mar. 2006); *Saramaka vs. Suriname*, Inter-Am. Ct. Hum. Rts. (Ser. C) No. 172 (28 Nov. 2007)).

Other regional human rights bodies similar to the OAS exist in Africa, under the auspices of the Organization of African Unity (OAU) and in the African Commission (African Commission) and Court on Human and Peoples' Rights (African Court); and in Europe, as the Council of Europe and in the European Court on Human Rights. Each regional body has its own set of regional human rights treaties, judicial precedents, and protocols with varying treatment of indigenous rights as a specific area of law.

For example, in the 2010 case of *Endorois Welfare Council v. Kenya*, the African Commission found that the Kenyan government violated several rights under the African Charter on Human and Peoples' Rights when it evicted the Endorois people from their ancestral lands to create a game reserve. The African Commission cited to the AU human rights instruments, as well as precedent from the OAS, ILO 169, and the Draft United Nations Declaration on the Rights on the Rights of Indigenous Peoples (discussed *infra*) to find that Kenya had violated the Endorois' collective right to property, the right to free disposition of natural resources, the right to religion, the right to cultural life and the right to development. Additionally, the African Commission recognized Endorois ownership over their traditional land, granted unrestricted access to their land for grazing and practicing cultural and religious traditions on traditional cites, and ordered the Endorois be compensated for their losses (Endorois, 2010, recommendations). This case demonstrates the continued evolution of indigenous rights as inclusive of communal property claims and customary norms following the *Awas Tingni* case in other regional international jurisprudence.

Elsewhere around the world, human rights regimes are evolving from nascent origins. The UN Permanent Forum on indigenous peoples recognizes seven international regions (Africa; the Arctic; Asia; Eastern Europe, Russian Federation, Central Asia and Transcaucasia; Central, South America & the Caribbean; North America; and the Pacific) that each have representation in the Permanent Forum and contribute important, if still developing, work to the domestic and regional implementation of indigenous rights, respectively.

The United Nations Declaration on the Rights of Indigenous Peoples

After more than 20 years of activism and organizing by indigenous peoples and advocates, the UN General Assembly adopted the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) on 13 September 2007, with 143 member-states voting in favor of the UNDRIP, 11 abstentions, and four no-votes from the United States, Australia, New Zealand, and Canada. By December of 2011, all four countries voting against it in 2007 had officially endorsed the UNDRIP.

As a matter of international law, declarations such as the UNDRIP are nonbinding statements, standard-setting documents that offer guidance to states on international standards and norms. Although the UNDRIP is not a binding treaty or covenant, it can be viewed as a remedial and interpretive instrument whose effect is to make clear that the rights afforded to other individuals and peoples through treaties, customary international law, and international principles, extend to indigenous individuals and peoples as well. The UNDRIP could also be seen as an independent source of customary international law, international legal principles, or of persuasive effect due to a demonstrated consensus among the majority of state actors (Anaya, 2009). Although the specific legal effect of the UNDRIP remains unsettled, it articulates a clear set of indigenous rights to both gage and guide the treatment of Native communities by colonizing governments.

Substantive Provisions of the UNDRIP

The UNDRIP consists of 24 preamble paragraphs and 46 substantive articles affirming the equal rights of indigenous peoples to those of all peoples, while preserving the cultural diversity of native groups and enhancing "harmonious and cooperative relationships between the state and indigenous peoples based on principles of justice, democracy, respect for human rights, nondiscrimination, and good faith" (UNDRIP, 2007, preamble). Articles 1 and 2 of the UNDRIP affirm both the individual and collective right of indigenous peoples to all protections afforded in international human rights law and affirm that indigenous peoples are "free and equal to all other peoples" (UNDRIP, 2007: art. 2). Articles 1 and 2 of the UNDRIP thus affirm that indigenous peoples are 'peoples,' and thus entitled to the same rights of all peoples afforded under the ICCPR and ICESCR, and add to the remedial strength of the UNDRIP as a source of international law.

The following summarizes the UNDRIP by grouping samples of individual articles into five broad categories of indigenous rights reflected in the literature: the right to self-determination; the right to property; the right to culture; the right to health, education and work; and the right to free, informed, prior consent.

The Right to Self-Determination

Article 3 of the UNDRIP imports the exact language of article 1 of the ICCPR and ICESCR, granting indigenous peoples the right to self-determination. Various articles affirm rights to self-governance and customary decision-making, and participation in the political landscape of the state. For example, articles 4 and 5 elaborate on the right to self-determination, specifically securing the right to autonomous self-governance (UNDRIP, 2007: art. 4), and "the right to maintain and strengthen their distinct political, legal, economic, social and cultural institutions, while retaining their right to participate fully, if they so choose, in the political, economic, social and cultural life of the State" (UNDRIP, 2007: art. 5). Article 35 recognizes "the right of indigenous peoples to make their own decisions about responsibilities given to members of their community," which includes the right to determine tribal membership (UNDRIP, 2007: art. 33) and to develop their own governmental structures and institutions (UNDRIP, 2007: art. 34). Furthermore, the right to self-determination secured by the UNDRIP is likely internal and not external,

because it prohibits a right to succession. Article 46 of the UNDRIP provides that "Nothing in this Declaration may be interpreted as implying for any State, people, group or person any right to engage in any activity … which would dismember or impair, totally or in part, the territorial integrity or political unity of sovereign and independent States."

The Right to Property

The UNDRIP provides that "Indigenous peoples have the right to own, use, develop and control the lands, territories and resources that they possess by reason of traditional ownership or other traditional occupation or use, as well as those which they have otherwise acquired," and that states shall recognize and grant legal protection over those traditional lands and resources (UNDRIP, 2007: art. 26). Included in the indigenous right to property is the "right to maintain and strengthen their distinctive spiritual relationship with their traditionally owned or otherwise occupied and used lands, territories, waters and coastal seas…" (UNDRIP, 2007: art. 25), the right not be removed from their lands without their free, informed, prior consent, the right to proper compensation in the form of equivalent lands or money should they be removed from their lands (UNDRIP, 2007: art. 10; UNDRIP, 2007: art. 28), the right to be free from military activity on indigenous lands without free, informed, prior consent (UNDRIP, 2007: art. 30), the right to "the conservation and protection of the environment and the productive capacity of their lands or territories and resources" (UNDRIP, 2007: art. 29); and the right to develop their lands and resources according to local needs (UNDRIP, 2007: art. 32).

The Right to Culture

The UNDRIP affirms the indigenous right to cultural integrity free from discrimination. This includes the right to practice and protect traditional forms of knowing and being in the world. For example, article 8 affirms the right to culture and mandates that states implement domestic policy that prevents and provides redress for "(a) Any action which has the aim or effect of depriving them of their integrity as distinct peoples, or of their cultural values or ethnic identities; (b) Any action which has the aim or effect of dispossessing them of their lands, territories or resources." Included in the Indigenous Right to culture is the right to maintain ceremonial practices and protect cultural sites, artifacts, and designs (UNDRIP, 2007: arts. 11–12), maintain and control traditional knowledge, cultural expressions, and the tangible manifestations of those "including human and genetic resources, seeds, [and] medicines…" (UNDRIP, 2007: art. 31).

The Right to Health, Education & Work

The UNDRIP secures a series of rights related to the general health and individual economic and social well-being of indigenous peoples. For example, article 7 affirms that "Indigenous individuals have the rights to life, physical and mental integrity, liberty and security of person." This includes rights to education (see, e.g., Graham, 2010), health, and employment. Article 21 provides that "Indigenous peoples have the right, without discrimination, to the improvement of their economic and social conditions, including, inter alia, in the areas of education, employment, vocational training and retraining, housing, sanitation, health and social security." This includes the right to nondiscriminatory and culturally appropriate media (UNDRIP, 2007: arts. 15–16), and the right to equal and equitable employment (UNDRIP, 2007: art. 17). The UNDRIP affirms that "[p]articular attention shall be paid to the rights and special needs of indigenous elders, women, youth, children and persons with disabilities" in the implementation of each of the articles in the Declaration (UNDRIP, 2007: art. 22).

The Right to Free Informed Prior Consent

Incorporated throughout the UNDRIP is the indigenous right to free, prior, informed consent (FPIC) in decisions that may affect their sociocultural life, lands, or resources. The FPIC language appears in articles 10 (relocation), 11 (cultural property), 19 (legislative or administrative decision making), 29 (environmental protection), 30 (military activity), and 32 (development). The exact meaning, content, and processes for achieving affirmative consent is now developing in international and domestic forums.

The UNDRIP in International and Regional Human Rights Tribunals

On 24 July 2012, in *Sarayaku v. Ecuador*, the most recent case interpreting the UNDRIP after it had been adopted by the UN and endorsed by the majority of member-states, the IACHR ruled in favor of the Sarayaku people of Ecuador in a landmark decision against the state. The decision culminated a 10-year legal battle in the Inter-American system stemming from the Ecuadorian government's authorization of oil exploitation by a foreign company on Sarayaku land beginning in the 1990s. The oil development degraded Sarayaku land, and the use of explosives threatened the lives of community members. As a result, the Sarayaku alleged that the Ecuadorian government violated their right to FPIC, their right to property, their right to life and personal integrity under the ICCPR, ILO 169, the American Convention, the UNDRIP, and previous decisions of the Court including Awas Tingni.

The Inter-American Commission on Human Rights (IACHR) found that the Ecuadorian government failed to properly consult with the Sarayaku people, which led to a violation of the right to property and accompanying rights to personal life, culture, and personal integrity. It ordered $1 340 000 damages and the removal of all explosives, and that Ecuador incorporate the right to free, prior, and informed consent into domestic law. In so ruling, the court elaborated on the substantive meaning of the right to free, informed, prior consent by affirming that consultation is not a mere formality, but a true instrument of participation, "carried out in good faith, through culturally adequate procedures with the intent to arrive at an agreement … in the first phases of the development plan or investment" (Sarayaku, 2012: para. 177).

Other Instruments and Institutions of Indigenous Rights

In addition to the ICCPR, ICESCR, ILO 169, and the UNDRIP, indigenous rights have been incorporated in a variety of other

important international laws and processes involving the indigenous right to culture, and specifically the use of traditional knowledge in conservation and development.

For example, article 8(j) of the Convention on Biological Diversity states that subject to national legislation, contracting parties shall "respect, preserve and maintain knowledge, innovations and practices of indigenous and local communities embodying traditional lifestyles relevant for the conservation and sustainable use of biological diversity and promote their wider application with the approval and involvement of the holders of such knowledge, innovations and practices and encourage the equitable sharing of the benefits arising from the utilization of such knowledge innovations and practices." Similarly, the United Nations Educational, Scientific and Cultural Organization (UNESCO) has recognized the need to protect Indigenous cultures through a variety of instruments including the 2001 Declaration on Cultural Diversity, the 2003 Convention for the Safeguarding of the Intangible Cultural Heritage, and the 2005 Convention for the Protection of the Diversity of Cultural Expression. The World Intellectual Property Organization (WIPO) is currently engaging in multigovernmental negotiations to address the use and protection of indigenous traditional knowledge, cultural expressions, and genetic resources (WIPO, 2013).

As a result of indigenous advocacy, the international community has recognized that indigenous peoples are disproportionately affected by the negative effects of climate change, and uniquely situated to address mitigation and adaptation through indigenous experience and knowledge. Accordingly, the UN Collaborative Programme on Reducing Emissions from Deforestation and Forest Degradation in Developing Countries (UN-REDD) engages local Indigenous communities in REDD project formation and implementation in participating countries around the world. Although REDD recognizes the role of indigenous peoples in climate change policy, the actual potential of REDD to incorporate indigenous rights on the ground remains unclear (Llanos and Feather, 2011; Baez, 2011).

World Bank funding for climate change strategy and other development projects similarly acknowledges indigenous rights in project management and funding criteria. For example, the 2005 World Bank operational policy 4.10 requires that a borrower set forth an action plan "[f]or all projects that are proposed for Bank financing and affect Indigenous Peoples … the Bank provides project financing only where free, prior, and informed consultation results in broad community support to the project by the affected Indigenous Peoples" (World Bank, 2005). This World Bank policy which acknowledges indigenous peoples as stakeholders distinct from the state demonstrates the increasing influence of indigenous rights, specifically the right to FPIC, in domestic and international law and policy.

Conclusion

The story of indigenous rights is unfolding before our eyes, with recent and ongoing advances in the recognition of indigenous rights as a matter of international and domestic law (Carpenter and Riley, forthcoming). Yet, as scholars have argued, it remains unclear exactly how indigenous rights will impact indigenous peoples on the ground, and in particular whether legal regimes have the capacity to bring about positive changes in the lives and wellbeing of indigenous peoples (Wainright and Bryan, 2009; Badger, 2011; Singel, 2012). Through these developments, Native peoples have demonstrated an insurmountable will to survive in the face of overwhelming pressures from states, and have begun to change the shape of international human rights law through the indigenous rights movement.

Indigenous Social Work

Michael A Hart, University of Manitoba, Winnipeg, MB, Canada

Abstract

This article presents an overview of indigenous social work. It begins with a presentation of indigenous epistemes and helping practices as a foundation to working with indigenous peoples. It outlines the diversity of indigenous peoples and impacts of colonialism on the people. It provides an overview of indigenous social work and closes with an example of a particular indigenous approach.

Introduction

Professional social work has been around for a century, while indigenous social work is a relatively new development. Partially emerging in response to the concerns of how social work reflects nonindigenous ideas, perspectives, and practices, it has developed with a strong connection to indigenous epistemes and ways of being and indigenous helping practices (Hart, 2002; Sinclair et al., 2009). Some challenges that have emerged during its development have been the continued impact of colonialism that indigenous peoples face. This has not only resulted in a diversity of indigenous perspectives but also influenced social work practice by creating a need for diverse approaches. All these points contribute to the explanation of indigenous social work. The following sections provide an overview of indigenous social work, beginning with an overview of indigenous epistemes and ways of being that are a foundation for indigenous social work. Then, helping practices of indigenous peoples generally to provide some comparative context for indigenous social work is outlined. The impact of colonialism on indigenous peoples is reviewed as an additional factor influencing the context of indigenous social work. The last half of this article focuses on an overview of indigenous social work. This overview includes a detailed example of one approach within indigenous social work, namely, the *mino-pimatisiwin* approach (Hart, 2002, 2008, 2009). This approach relies on indigenous knowledge about helping stemming from indigenous peoples in the central area of North America. It has the foundational concepts of focusing on the whole, relationships, balance, harmony, healing, growth, and *mino-pimatisiwin* (a Cree term literally meaning good life). Following indigenous ways of being, it has particular views of people, helping processes, and helping techniques.

Indigenous Epistemes and Ways of Being

Episteme is understood in a broad sense to mean the taken-for-granted presuppositions that are the primary socializing force and act as the foundation to our values, attitudes, and perceptions of the world (Koukkanen, 2007). Indigenous peoples' epistemes and ways of being in the world share some commonalities. These commonalities include the centrality of spirit, connection to land and other life, the recognition of cycles and flux, the importance of elders, communalism, egalitarianism, respectful individualism, and ceremonies (Couture, 2011; Hart, 2009; Koukkanen, 2007; Little Bear, 2000). These are important to recognize because these provide the foundations of indigenous helping theories and practices and are key to developing an understanding of how to work with indigenous peoples when one functions from alternate epistemes like those rooted in European ways of thinking and being.

Centrality of Spirit

As explained by Mark and Lyons (2010), "spirituality is defined variously as existential reality, connectedness, and energy, or as a dimension of a person that is concerned with the transcendent and life's meaning" (p. 1756). Spirit in many indigenous peoples' cultures plays a prominent role (Hart, 2008, 2009; Mark and Lyons, 2010). This prominence is evident by the significant attention paid to the metaphysical world in everyday activities alongside having specific events and/or activities that guide indigenous people's interactions with the spirit realm.

Holistic Perspective: Connection to Land and Other Life

Indigenous epistemes are not the bioreductionist perspectives of modernist societies. They are all-encompassing because attention is given to the mental, physical, emotional, and spiritual aspects of people in relation to the lands and life on the lands where the people are located (Hart, 2002). This holistic perspective directs the actions of indigenous people whose efforts are focused on being in relation with other life as opposed to exercising control over other life. Well-being is then reflected in how people give attention to all aspects within themselves, as well as in how people interconnect to the land and life around them (Hart, 2002; Mark and Lyons, 2010).

Recognition of Cycles and Flux

Many indigenous languages are verb based (Little Bear, 2000). Working from this base, indigenous peoples focus on actions and inactions and patterns of these actions and inactions. The patterns are studied to recognize the cycles that are evident, e.g., cycles within individuals, between individuals, and in nature generally. Examples of such cycles include the times of high and low energy a person regularly experiences each day, the communication patterns that two individuals

share, and impact of the moon or seasons on individuals. These cycles are also looked at in relation to one another. The observations are made during various lengths of time ranging from short time spans to observations made over generations. When significant changes occur in these patterns, observations continue to see if the patterns have changed permanently or whether they are a continuation of larger ebbs and flows. All observations are made to determine how any, or all, individuals fit with the patterns and how to adjust to the fluxes that occur. The concept of flux is grounded within indigenous perspectives that see the world and life as in constant motion and changing (Little Bear, 2012). As the world and life are constantly changing – in flux, individuals are constantly adjusting to these changes. This focus emphasizes the beliefs that people are part of the world and not controllers of it, and that they do best by fitting in with the cycles and adjusting to the fluxes.

The Importance of Elders

Elders are recognized as the individuals who consciously carry indigenous knowledge for their peoples and who demonstrated their knowledge by how they live. They are seen as the living embodiment of indigenous cultures and knowledge (Couture, 2011). They play a primary role in these knowledge systems, particularly since they are the link in the intergeneration development of indigenous knowledge. This key role ensures that they are regularly turned to for guidance, support, and understanding.

Community, Egalitarianism, and Respectful Individualism

Indigenous societies rest on a strong sense of community where groups of individuals are interdependent. Within these societies, individuals are considered participants of the group's activities. Such participation includes the commitment to support other members while recognizing that they will receive support when needed. This form of egalitarianism emphasizes less hierarchical forms of organization and supports respectful individualism (Gross, 2003; Hart, 2008, 2009). Respectful individualism gives individuals significant freedom in self-developing their personal gifts under a shared understanding that they are committed to contributing to group well-being.

Ceremonies

To fit in the patterns of life, including personal development of one's gifts, indigenous peoples have developed particular processes referred to as ceremonies. These ceremonies regularly require multigenerational participation, and necessitate the knowledge of elders and other informed individuals on how to carry out the ceremonies. Ceremonies then become part of the group's life patterns that connect them to the land and other life entities surrounding them. These play a central role in maintaining and reestablishing wellness.

Values

Certain values emerge from indigenous epistemes, including a heightened and expanded understanding of respect, an emphasis on sharing, and important social responsibilities (Hart, 2002, 2008, 2009; Mafile'o, 2008; Weaver, 2008). Respect is about treating others with dignity, esteem, and in the manner that they wish to be treated, or do unto others, as others want done unto them. It requires people to learn about the other person. Respect stems from understanding that all beings have spirit, and that all spirit is to be respected. To be disrespectful means to go against a fundamental aspect of life. Hence, all beings are to be respected since no one species of life is held as more important than another. For indigenous people, respect is reflected in practices such as how individuals treat one another, plants, the raising and gathering of crops, and animals that are herded or hunted. It is also reflected in the ceremonies that give positive attention to all forms of life.

Regarding people, a great deal of respect is given to children by providing them with lots of freedom to develop and learn through modelling processes, and to older people who have knowledge and experience. All genders are well respected in recognition that no gender is subservient to another and that all people play a role in the well-being of the community. Respect is important for peoples' well-being.

Another important value within indigenous epistemes is sharing (Hart, 2002). It is a fundamental aspect of indigenous cultures, and directly reflects the importance of relationships. Sharing is the distribution of what one has in their possession with others. It helps people maintain relationships and goodwill and is indicative of the concepts of community and interconnection. It is so pervasive in some indigenous cultures that a wide variety of things are shared, including land, food, supplies, ideas, ceremonies, and songs. Sharing runs counter to notions of the 'survival of fittest' since life is not about competition where the mightiest wins, but about providing to others through commitment and even sacrifice.

A third value worthy of note is social responsibility (Weaver, 2008). In direct relation to respectful individualism and communalism, indigenous people provide significant space for individuals to develop their own gifts with the understanding that as these develop they will be contributing back to the community. This understanding is driven by the value of social responsibility where people hold a personal sense of commitment and accountability to their families, communities, and all life. This responsibility is a key link in the peoples' interconnections to one another and to all life and is central to indigenous helping practices.

Helping Practices within Indigenous Cultures

Indigenous peoples always had their own ways of helping. These practices were and are manifestations of indigenous epistemes and ways of being in and experiencing the world. They are not based on the theoretical premises of many European/American theories that emphasize individualism, nuclear families, the Cartesian split of the mind and body, and objective distancing of the helper (Lettenberger-Klein et al., 2013; Little Bear, 2012; Liu, 2011). Nor are these based on the avoidance of spiritual considerations that drives positivistic theories and empiricism followed by nonindigenous professional helpers.

Traditional indigenous helping processes embed the spirit conceptually (Hart, 2002; Mark and Lyons, 2010; Weaver, 2008)

in interconnections between the individual and other life. These processes consider how an individual, family, or community fits within the cycles around them, and how they may have worked against or disconnected from these cycles. Ceremonies are relied upon to facilitate the reconnection of individuals, families, and communities to these cycles. Traditional indigenous helping processes recognize that changes to the cycles can impact individuals, families, or communities and that helping processes can assist people in readjusting to these changes. Furthermore, many trickster stories in indigenous cultures indicate that these processes acknowledge that there are forces that can cause significant fluctuations in the cycles, seriously impacting upon people and requiring intervention. These interventions, whether for supporting individuals to reestablish themselves with the cycles around them or addressing destructive forces, often involve ceremonies. These ceremonies can range from being focused narrowly on the individual and/or issue to a wider scope of incorporating whole communities as an indirect means of addressing the issue. Most often, these ceremonies address people's physical aspects while giving significant consideration to the emotional, mental, and spiritual dimensions of participants and healers, ensuring that both are closely involved in ceremonial processes. These indigenous ways of helping differ considerably from practices stemming from European epistemes. These differences were and continue to form the bases of the colonial oppression of indigenous peoples.

Colonial Impacts

Colonialism has greatly impacted upon indigenous peoples and their helping practices and requires recognition. In many parts of the world, indigenous peoples are oppressed and prevented from living in ways that emerge from their epistemes and cultural practices. This oppression varies throughout the world, ranging from forms that marginalize indigenous voices and practices to outright violent persecution of indigenous peoples.

Theorists indicate that oppression has disconnected indigenous peoples from their own epistemes and ways of experiencing and being in the world in varying degrees (Akena, 2012; De Souza and Rymaez, 2007; Fanon, 2008/1951; Hart, 2002; Memmi, 1991/1965; Simpson, 2008). Some indigenous peoples have maintained a strong connection with their epistemes to remain the dominant driver in how their peoples move forward in their daily lives. These individuals include elders who maintain knowledge of the traditional ceremonial practices of their nation (Couture, 2011). Others have internalized cultures stemming from oppressive forces to the extent of incorporating various dominant epistemes and practices. For another segment, this incorporation has come by force and impacted upon them to the degree that they have internalized oppression against their own people and now actively work against ways of living that reflect indigenous epistemes. An example of internalized oppression is demonstrated through indigenous gangs that attempt to rule their own communities through fear and violence (Comack et al., 2013). One result of imposed colonialism has been increased diversity within indigenous communities, spanning from individuals maintaining a way of being based in their indigenous episteme to individuals who separate themselves from indigenous ways of being.

Indigenous Diversity

Indigenous peoples' experiences with colonial oppression have created significant diversity between and within indigenous cultures. This diversity can be seen along one axis stemming from deeply immersed within indigenous cultures to deeply immersed within colonial cultures. This axis would have a split on one end with those consciously choosing not to identify with the colonizing culture on one side and those who have unconsciously internalized their oppression on the other. This diversity is further complicated in that colonizing cultures are heterogeneous, e.g., significant diversity among French, Spanish, Dutch, English, and American cultures.

Indigenous peoples' cultures and practices also have to be recognized as significantly diverse on other grounds. Recalling that a key aspect of indigenous epistemes is their connection to land of their territories, indigenous peoples' ideas and cultural practices will reflect diversity in the land. There are approximately 370 million indigenous peoples in 90 countries across the world (United Nations Department of Economic and Social Affairs, 2009); there is considerable diversity in indigenous peoples' cultures, languages, ideas, and practices.

With such great diversity between indigenous cultures and peoples' experiences of colonialism, talking about indigenous cultural helping practices with a presumption of these applying to indigenous peoples throughout the globe is problematic and challenging. Nonindigenous people have to maintain constant awareness of this, remembering that any work with indigenous peoples requires learning from them directly to address their diversity. This point is central to indigenous social work.

Indigenous Social Work

Indigenous social work stems firmly from indigenous epistemes and ways of life and includes a crucial stance against colonialism that is informed by indigenous epistemes, the diversity of indigenous nations, indigenous knowledge stemming from these nations, and critical perspectives that address colonial oppression. Indigenous social work acknowledges the more common epistemic elements of indigenous cultures. Hence, it tends to be holistic with strong recognition of the relationships between individuals, families, communities, and the land. It recognizes interdependence between people, and peoples and other life. It looks at these relationships for patterns, cycles, and disruptions to patterns and cycles. It is based in concepts of community, respectful individuals where individuals are seen as inherently good and oriented to developing their gifts and capable of contributing to their communities. These matters are examined all at the same time to reassure the well-being of all community members as well as the living environment around them.

Being based in indigenous epistemes requires indigenous social work to reflect not only the common elements among indigenous epistemes (noted above) but also the perspectives of particular indigenous communities. In other words, indigenous

social work is global in scope as it relates to many indigenous nations, but is local in focus as it directly reflects the communities from which it stems. Thus, it avoids a 'pan-indigenous' stance that sees and treats all indigenous peoples as stereotypically the same (Baikie, 2009). Instead, it stems from and reflects the people and lands being served. This ability allows indigenous social work to pull teachings from various indigenous nations and have them considered by the people being served for their appropriateness and/or adaptation. Significant in these processes is the recognition that the power to determine the fit of a practice lies with indigenous peoples.

Indigenous social work practice recognizes diversity and must accommodate this diversity in practice. Thus, there is no one practice, theory, or approach that covers indigenous social work. This diversity has been reflected upon in various ways (Baikie, 2009; Hart, 2003). Practices must cover a range of approaches that may incorporate other indigenous forms, producing social work practices based in indigenous cultures, but resonating across many indigenous cultures. For example, Green and Baldry (2008) have outlined key indigenous concepts relevant to many indigenous peoples throughout Australia. These include collective self-determination, interdependence, reciprocity, obligation, land, and family. There are indigenous social work practices that while specific to particular indigenous culture(s) have been transferred to nonindigenous cultures. An example is the Maori constructs that have been adopted by European (Pakeha) social work professionals in Aotearoa/New Zealand (Munford and Sauders, 2011). These concepts include *homai ki te tangta, te kanohi kit e kanohi* – give it to a person face to face, *mamaakitanga* – hospitality with genuine care and support, and *whanaungatanga* – understanding the responsibility of belonging to a *whanau*/family. Some indigenous helping practices require greater skill development than that provided in mainstream social work educational systems. An example includes the use of the sweat lodge in social work (Schiff and Pelech, 2007; Voss et al., 1999). These practices are specific to a particular culture and rest in the hands of indigenous healers or elders. They may be used by social workers trained in these practices, but more often they are practices that social workers need to be aware of to make appropriate referrals.

Indigenous social work relies on indigenous knowledge that rests in keepers such as elders and traditional healers. Hence, people working from indigenous social work stances seek their guidance, support, and teachings. These individuals and teachings may be incorporated into formal education, but are more likely additional resources that an individual would have to learn to access. As indigenous knowledge has an element of subjectivity and is localized, indigenous social work includes the necessity to develop long-term relationships with local elders and healers. It also requires a basic level of learning and understanding about indigenous helping knowledge. Overall, indigenous social work avoids the subjugation and marginalization of indigenous knowledge and recognizes these and their holders alongside any other professionals and their education. Indigenous knowledge processes are also valued in indigenous social work (Baikie, 2009), recognizing that social work practices can be supported through inductive means of learning where people focus on the immediate context and slowly broaden their knowledge base with each circumstance they encounter. This process of developing theory from practice values pragmatic, tacit, and/or culturally implicit knowledge.

Additionally, indigenous knowledge and indigenous social work incorporate critical theories that address oppression, inequities, the influence of social structures and policies on individuals, and social justice. In particular, indigenous social work encompasses literature and practices on colonialism, anticolonialism, and decolonization (Hart, 2009). In some circumstances, material stemming from postcolonial literature is considered as well, although there are limitations to this literature for practice applications in social work (Hart, 2007). A related area of theoretical knowledge stemming primarily from academic sources is that of racism. Racism is a central component to maintaining colonial oppression (Memmi, 1991/1965) and evident in cultural, structural, and personal realms (Dominelli, 1988; Mullaly, 2007). By addressing colonialism and racism, indigenous social work recognizes that indigenous peoples are caught in relationships that distribute power in unequal and harmful ways. Thus, indigenous social work pays attention to critical issues including the distribution of power, privilege, and relationships between indigenous and nonindigenous peoples in colonial processes. By addressing these relationships and power distributions, matters of rights, including indigenous rights, human rights, and ecological justice, are given considerable attention.

From this foundation, many approaches and theories have emerged. Baikie (2009) has theorized indigenous-centered social work using postcolonial and anticolonial thoughts. Mafile'o (2008) has outlined an approach to Tongan social work practice. McKenzie and Morrissette (2003) have addressed a way to approach social work with aboriginal peoples in Canada. Weaver (2008) has written on indigenous social work in the United States. Kee (2008) has outlined the development of culturally appropriate social work practice in Malaysia, making indigenous social work vast and developing. These various approaches and theories have been progressing for differing lengths of time and to various degrees, but much of it has emerged in the past two decades.

An Example of Indigenous Social Work Based within Indigenous Epistemes

One approach that has been developed over two decades is the *mino-pimatisiwin* approach initially developed in 1997 and later (Hart, 1997, 2002, 2006, 2008, 2009). At its commencement, there were no indigenous approaches to social work relevant to practice with indigenous peoples in the central part of North America in the literature. This aimed to reflect the epistemes and helping practices of indigenous peoples, particularly the Anishinaabe, Cree, Dakota, Dene, and Oji-Cree peoples, who reside in the central part of Ininiwi-Ministik (North America). Hence, it developed from the perspectives of indigenous peoples in this territory to support social workers to practice in a culturally relevant way. It has several key concepts and values, and has a particular orientation to viewing people and helping processes.

Three aspects of indigenous epistemes are the primary foundation of the *mino-pimatisiwin* approach. First, it has the

central pillar of spirituality where *manito*, spirit, is recognized as a positive force that is found within, and shared between all life entities. Second, the *mino-pimatisiwin* approach rests on the stance of respectful individualism where people are given extensive room and freedom for inner exploration and self-development. Third, it rests on a sense of community that is tied together through biological and adapted family relations, and a commitment to the community by family members as demonstrated by their sharing, support, and interest in the well-being of one another.

The key concepts of the *mino-pimatisiwin* approach are holism, relationships, balance, harmony, growth, healing, and *mino-pimatisiwin*. Holism is a recognition that when working with an individual, attention must be given to all aspects of that individual, including their emotional, mental, spiritual, and physical dimensions, including the many aspects around that person, e.g., their family, communities, nation, and the natural and built environment. This approach holds relationships as a key concept where all elements within individual and those aspects around them are understood as being connected to one another. These connections are to be supported and nurtured since positive connections are viewed as enhancing health and well-being. In particular, individuals are to maintain or bring balance to their life by giving attention to the four fundamental aspects of people: their physical, mental, emotional, and spiritual selves. Further, individuals are understood to be in the contexts of their families, communities, nations, and larger environment. When people are focused on maintaining balance and honoring relationships between the various aspects within and around them, and when each element is fulfilling its obligation in relation to all others, harmony is the result. This harmony is the ideal condition for growth where growth is a daily and lifelong process of developing all aspects of one's self. Healing is similar to growth in that it is orientated to the restoration of relationship, balance, and harmony, where disconnection, imbalance, and disharmony emphasize the need for attention. Ultimately, the intent is to strive for *mino-pimatisiwin*, the good life where people are living as fully as possible with positive, balanced, and harmonious interconnections among all aspects of their lives. While *mino-pimatisiwin* is the aim, and on occasions people feel they have reached it successfully, it is not a permanent state. It is a lifelong goal as life is constantly changing.

This approach acknowledges that values are frequently highlighted as guides for various indigenous peoples. While many values have been identified, two values are highlighted in this approach, namely, respect and sharing. Respect is a universal value among diverse cultures. When this value is followed within the context of respectful individualism and community, it takes the form of honor, esteem, deference, and courtesy to all aspects of life, and particularly of the person being helped and the relationship being developed with the helpers. It also includes refraining from imposing one's views onto others whenever possible. Thus, the focus is on supporting the individuals through their own self-discovery of the issue(s) at hand. Respect is necessary for maintaining positive and healthy relationships, including that between the helper and the person seeking help.

Sharing is strongly emphasized in this approach. Such deep sharing helps to build and maintain positive relationships and demonstrates that everyone is important. The role of the helper includes sharing knowledge, understanding, guidance, support, and encouragement. It is also important that helpers recognize, respect, and acknowledge that the person who they are helping is also sharing, including their time, experiences, trust, faith, and life.

The *mino-pimatisiwin* approach has a specific orientation toward people. The basic nature of people is seen as good, but recognizes that people can learn negative attributes that focus on selfishness, breaking relationships, and hurting life. The *mino-pimatisiwin* approach sees people in a state of being, where being is understood as the here-and-now relationship with that which surrounds them. People are also seen as being in a state of being-in-becoming, which emphasizes people identifying their sense of purpose as including *mino-pimatisiwin*, and making efforts to strive toward that sense of purpose. From the perspective of this approach, people are seen as dependent on those who have lived before them and on other life since people are social beings. This perspective implies that people's histories are as important as their connections with others. To support these relationships, people are guided by good conduct that is learned through such practices as participation in ceremonies, the guidance of elders, and deep, honest self-reflection.

The *mino-pimatisiwin*'s orientation to helping rests heavily on indigenous epistemes. Recognizing the importance of relationship, this approach focuses on the relationships of the person seeking help, including the relationship between the helper and the person seeking help. While helpers may have experience and knowledge about relationship dynamics, they are not considered experts. The subjective experiences of the person seeking help remain the paramount source of information and understanding. Thus, helpers focus on establishing and strengthening the relationships between themselves and the people they are serving. By highlighting the positives within their relationships, helpers are able to extract practical examples that would strengthen the abilities of the persons seeking help. Further, by developing this relationship, helpers will be provided with a deeper sense of the experiences of the people seeking help so as to positively mirror these back to them for reflection and consideration. To facilitate this development of and strengthen this relationship, helpers speak from the heart, meaning not only with their 'professional' knowledge but also with a holistic sense of their emotional experiences, present feelings, 'gut reactions,' and intuition. While not dismissing evidence-based practice or similar stances, working from a *mino-pimatisiwin* approach requires practice-based evidence where helpers utilize their experiences that may arise holistically through their cognitive understandings, feelings, and physical awareness and reactions. Finally, it is highly relevant that helpers recognize that the helping process is not a one-way experience. By honestly recognizing that they will be impacted, grow, and even develop as people, helpers can begin to honor the relationship between the person seeking help and themselves and recognize the gifts that they are receiving.

To approach helping in this manner, helpers are expected to address their own growth and healing. Recognizing that growth and healing are lifelong activities as people seek *mino-pimatisiwin*, helpers regularly reflect on their own lives,

how their practices are a continued reflection of their life experiences and learning, and how they are impacting upon relationships that they have with the people they serve. From this approach, there is an understanding that helpers are striving to live the life that they wish for others and that they are incorporating the key concepts and values of this approach within their own lives. Helpers are expected to have excellent listening skills, and be deeply empathetic, accepting of silence and long pauses. Such skills are not only appropriate to this approach but also serve as foundations for good practice and communication skills in social work generally. Furthermore, social workers utilizing this approach should be able to utilize skillfully nondirect means of working, such as the use of personal stories, role modeling, and practice examples. Other techniques include eliciting the support and direction of elders, incorporating humor, facilitating connections and incorporating culturally based rituals and ceremonies in their practice and as a source of additional services. These rituals and ceremonies include such activities as sharing circles, family group conferencing, and sweat lodges.

Conclusions

Indigenous social work is a broad concept reflecting the diversity of indigenous nations and peoples, as well as their experiences with nonindigenous peoples in social work. Despite this diversity, there are some aspects of indigenous epistemes and ways of being that are common to many indigenous peoples. These aspects not only serve as a foundation for cultural helping practices within indigenous cultures but also provide a unifying element to indigenous social work across the globe. They also speak to nonindigenous peoples who want to work in ways reflective of indigenous perspectives, such as antioppressive and strength-based approaches (Dominelli, 2004; Mullaly, 2010). While these common elements demonstrate the global nature of indigenous social work, it is important to recognize its local focus where the practices, values, and epistemes of specific indigenous peoples are supported by indigenous social work. Recognition of this diversity among indigenous peoples in relationship with one another as they work to strengthen their peoples and cultures epitomizes indigenous social work.

Individualism versus Collectivism: Philosophical Aspects

Philip Pettit, Princeton University, Princeton, NJ, USA and Australian National University, Canberra, ACT, Australia

Abstract

Individualism as a doctrine in social ontology – in the theory of what sorts of entities are important in the social world – is usually contrasted with collectivism. Collectivism comes in two varieties, hard and soft. The hard variety of collectivism argues that social-structural laws and forces, as revealed in social science, undermine the image of the human being as an autonomous agent. Individualism denies that this is so, while admitting that agency is subject to various limitations and failures. The softer variety of collectivism argues only that social science shows that human agency is not quite as central as common sense may suggest, illustrating the point in a variety of different theses. This sort of collectivism need not be rejected by individualists.

The issue between individualism and collectivism, as taken in this article, is the ontological issue as to whether the regularities of social life, in particular the regularities that have come to light in social science, cast doubt on the status of human beings as more or less autonomous intentional subjects. This issue should be distinguished from the methodological issue as to whether the explanation of social phenomena ought to invoke only the properties of individuals, as it should be distinguished from the moral issue as to whether social institutions should always be assessed from the point of view of their impact on individuals. Émile Durkheim, the great French sociologist, was the most influential defender of a hard form of collectivism in its ontological sense. He holds or at least suggests that individuals, as seen from the perspective of social science, lack the autonomy that they ascribe to themselves in common sense. Just as astronomy taught us that the sun does not literally cross the sky, and physics that solid objects are not solid in any literal sense, so the collectivist idea is that the social sciences teach us that individuals are not what they seem; they are not the self-determining centers of decision making that they take themselves to be. Hard collectivism in this sense looks implausible, as we shall see; only some soft versions of the doctrine – versions that sideline or downgrade intentional psychology without undermining it – look to have any serious support (Pettit, 1993).

The Emergence of Collectivism

The sociological way of thinking that brought Durkheim to this conclusion had its origins in the rise of social statistics in the early part of the nineteenth century. Responsive to electoral and utilitarian pressures, the governments of the newly industrializing countries sponsored the statistical mapping of a great variety of phenomena. "It was necessary to count men and women and to measure not so much their happiness as their unhappiness: their morality; their criminality; their prostitution; their divorces; their hygiene; their rate of conviction in the courts. With the advent of laws of statistics one would find the laws of love or, if not that, at least the regularities about deviancy" (Hacking, 1981, 1990).

This statistical mapping of large-scale society, this avalanche of numbers, had an important intellectual impact, because it revealed that social aggregates display surprising constancies, constancies that are often invariant over changes in the individuals, and in the mentalities of the individuals, involved. The statisticians constructed indices of divorce, suicide, crime, sickness, prostitution, and a variety of other phenomena. It soon became clear from their work that there were constancies over time in many such indices, and there were constancies in the correlation of different indices with one another.

At the beginning of the nineteenth century it would have been natural to expect aggregate statistics to be as variable as individual preference and choice. The revelation of unexpected pattern encouraged a sort of statistical determinism, associated in the beginning with French writers like AM Guerry and Adolphe Quetelet. Already by 1832, Guerry could write: "We are forced to recognise that the facts of the moral order are subject, like those of the physical order, to invariable laws" (Hacking, 1990). Such determinism came to be described as an astronomical conception of society, a conception in which people were driven by forces akin to a cosmic force like gravity; the fact that Quetelet was an astronomer lent credence to this characterization of the view (Hacking, 1990). The astronomical conception soon spread abroad, receiving a powerful impetus in the English-speaking world, and indeed more broadly, with the publication in 1857 of T. H. Buckle's *History of Civilisation in England*.

The astronomical conception of society received perhaps its most dramatic expression in Tolstoy's *War and Peace*, which was written between 1863 and 1869. One passage will serve to give the tenor of the view "Ever since the first person said and proved that the number of births or crimes is subject to mathematical laws, that certain geographical and politico-economical laws determine this or that form of government, that certain relations of the population to the soil lead to migrations of peoples – from that moment the foundations on which history was built were destroyed in their essence. By disproving those new laws, the old view of history might have been retained. But without disproving them, it would seem impossible to continue studying historical events, merely as the arbitrary product of the freewill of individual men. For if a certain type of government is established, or a certain

movement of peoples takes place in consequence of certain geographical, ethnographical, or economic conditions, the freewill of those persons who are described to us as setting up that type of government or leading that movement cannot be regarded as the cause" (Tolstoy, 1972).

The avalanche of numbers and the statistical determinism associated with it led to the development of the new science of sociology. True, the person who invented the term 'sociology', Auguste Comte, was averse to seeing the discipline as a merely statistical enterprise. However, the rise of statistical mapping had a crucial impact on Émile Durkheim, who was responsible for establishing sociology as a respectable science. The first empirically based study that he undertook was an investigation of suicide – published in 1897 – and this reveals both how deeply he was impressed by the statistical constancies of suicide and how naturally he moved toward the conclusion that those constancies were independent of the whirl and flow of individual choice. "Each society is predisposed," he remarked, "to contribute a definite quota of voluntary deaths" (Durkheim, 1951).

Durkheim accepted that aggregate constancies have a life of their own, remaining surprisingly invariant over relevant changes at the individual, intentional level. He postulated aggregate, social regularities to explain those constancies. An aggregate regularity may explain a constancy by subsuming it, as when a constancy in the correlation between two indices – say, the divorce rate and the suicide rate – is taken to reveal a regularity. An aggregate regularity may explain a distinct constancy, revealing a relationship between it and some independent factor, say, a relationship between an aggregate index or correlation of indices on the one side and a background factor like increased population density, an established current of opinion, growing urbanization, or even the fact that the factor in question – say, the correlation – is socially functional in some way. Durkheim gives expression to the sorts of regularities that he saw at the origin of statistical constancies, when he writes in the study on suicide: "the relations of suicide to certain states of social environment are as direct and constant as its relations to facts of a biological and physical character were seen to be uncertain and ambiguous. Here at last we are face to face with real laws" (Durkheim, 1951).

In order to understand the sorts of regularities that Durkheim envisaged, here are some examples. They are not chosen on the grounds that Durkheim actually endorsed them or even considered them – he did not – but because they represent a fair spread of the sort of sociological doctrine with which he was associated.

1. Increased unemployment leads to a rise in crime.
2. Urbanization leads to a decline in religious practice.
3. Policies for increasing employment cause inflation.
4. Economic stratification comes about in order to secure personnel for crucial positions.
5. Capitalism is stable when it is optimal for developing productive power.
6. States act internationally in their best economic interest.
7. States decline in political influence as they fall behind in economic capacity.
8. Companies maximize expected returns.
9. The protestant ethic facilitates the rise of capitalism.
10. Capitalism generates a breakdown in community values.

Regularities of these kinds are social-structural in character. They are social regularities, because they each demand that a number of individuals display certain intentional responses: they require that individuals commit crime in a certain proportion, give up attending church, and so on. They are structural, because they are discontinuous with intentional regularities. It is not supposed that unemployment leads to crime, or urbanization to religious decline, because it causally impacts in some intentionally intelligible way on the antecedents of intentional regularities; it is not supposed, for example, that it is because people become aware of unemployment or urbanization that they produce the behavior required for the consequent.

Durkheim and most of those who followed him took the sorts of regularities illustrated to give the lie to intentional psychology. He saw them as pointing us toward constraints that undermine or limit human autonomy. He saw them as vindicating, in essence, something like the so-called astronomical conception of society. The constraining factors to which social-structural regularities pointed, in Durkheim's view, range from the morphological features of a society, like the density of its population, to the norms or rules institutionalized there, to the currents of opinion and the enthusiasms that take over from time to time (Durkheim, 1938; Lukes, 1973). He described all these as social facts and argued that social facts constrain intentional agents from without. "Currents of opinion, with an intensity varying according to time and place, impel certain groups either to more marriages, for example, or to more suicides, or to a higher or lower birth rate, etc. A social fact is to be recognised by the power of external coercion which it exercises or is capable of exercising over individuals" (Durkheim, 1938).

In giving social facts this constraining role, Durkheim was explicitly challenging the individualist view – a view he naturally presents as an extreme position – that individuals enjoy intentional autonomy. Thus, he wrote of social facts that: "when we define them with this word 'constraint,' we risk shocking the zealous partisans of absolute individualism. For those who profess the complete autonomy of the individual, man's dignity is diminished whenever he is made to feel that he is not completely self-determinant" (Durkheim, 1938).

The Implausibility of Hard Collectivism

There are two different ways in which social-structural regularities might prove to compromise the intentional autonomy of individuals in the sort of measure that Durkheim apparently had in mind: in the measure, as we may take it, that would give the lie to individualism and support a position truly deserving of the title of hard collectivism. Individuals will be autonomous in the relevant sense so far as they form their beliefs and desires – their intentional attitudes – and act on those beliefs and desires in a manner that satisfies the general expectations that we hold in relation to a rational or approximately rational agent. One way in which social regularities would compromise individual autonomy is by overriding those intentional regularities, the other by outflanking them (Pettit, 1993).

The social regularities would override the intentional if they sometimes conflicted with them, predicting different

outcomes for the same situation, and if they proved in those cases to be the more reliable laws. The social regularities would outflank the intentional if it transpired that things are organized at the intentional level – intentional agents and attitudes are selected – so that the social regularities are assured of being satisfied. In the overriding case, the social regularities would predetermine what happened; in the outflanking case, they would predestine it.

The social sciences have not produced results robust enough to support collectivism in the literal or hard sense associated with the overriding or outflanking thesis. Hume argued that the testimonial evidence that a natural miracle occurred – that a law of nature was suspended – is almost always going to be outweighed by the day-to-day evidence of the reliability of the laws of nature. We might argue in parallel that the social scientific evidence in favor of an intentional miracle – in favor of the overriding of intentional regularities in otherwise normal agents – is almost always going to be outweighed by the day-to-day evidence of the reliability of intentional laws.

As it is with the overriding thesis, so it is with the outflanking one. This thesis would hold that in cases where human beings act so as to ensure that a social regularity obtains, that is no accident: were they going to have attitudes that would lead them not to support that regularity, then they would not have been there; they would not have been selected. The case envisaged parallels that of natural selection. Assume that mammals have been selected so as to favor the regularity whereby they can digest certain foods. That means if there were certain creatures going to have a system that did not support that regularity, then they and their ancestors would not have been there; they would not have been selected. While there is evidence of certain forms of social selection, there is no evidence for the powerful sort of selection – parallel to natural selection – that would be needed to support the outflanking alleged.

It ought not to cause any embarrassment for social scientists, however, that the overriding and outflanking theses – and the hard collectivism they would entail – are not borne out empirically. For if we recur to the examples given earlier, we can see that social laws of the sort that impressed Durkheim can be interesting and significant, quite consistently with not entailing hard collectivism. That those laws obtain is fixed in part by the fact that human beings are intentional systems who obey standard intentional laws, and in part by contingent facts about the attitudes of those individuals. That does not mean that just knowing about individuals and their intentional psychology will give us knowledge of those laws, not at all. It may take considerable data collection and data analysis before it begins to become plausible, say, that increased unemployment leads to a rise in crime or increased urbanization to a decline in religious practice. Such a regularity will be plausible in good part, because we can see how it fits with our knowledge of intentional psychology: we can see, for example, how unemployment might lead to crime by increasing both the opportunity and the incentive for criminal acts. However, that does not mean that we can derive the law from armchair reflection on our psychology.

Social laws not only will be interesting in this sense, even if they do not entail hard collectivism, but can also be of explanatory importance. Explanatory or methodological individualists hold that explanations that go to the level of individual psychology are to be preferred in social science to higher level, structural or aggregate explanations. Jon Elster assumes that just the fact of getting nearer the detail of production makes such an explanation intrinsically superior: "a more detailed explanation is also an end in itself" (Elster, 1985). Michael Taylor (1988) agrees: "A good explanation should be, amongst other things, as fine-grained as possible." However, the rejection of hard collectivism does not necessarily entail the adoption of such explanatory individualism.

Assume that explanation usually involves giving information on causal process. The reason that social laws are explanatorily important is that reference to such a law may give information on the causal process at its origin that is not available just from the story about the detailed psychological profiles of the individuals involved. Thus, we might be told of the individual psychological etiologies that produced the level of crime in a given year, and be told that that level is higher than earlier, without being given the information provided by the law, as we may assume it to be, which relates increased unemployment to increased crime. Indeed, we might not even have noticed that most of the new or more frequent offenders were unemployed. The reference to that law provides the information that the increased crime would materialize, not only in the presence of the precise psychological profiles of actual offenders but also under any condition where there is an increase of unemployment. It servesas an explanatory purpose that is neglected in the more detailed, individual-level stories (Jackson and Pettit, 1992; Pettit, 1993).

The Plausibility of Soft Collectivism

There is also another line of thought that ought to reconcile many social scientists to the failure of hard collectivism. This is that the argument just given is consistent with the truth of some claims that have a collectivistic ring but that do not involve either the overriding or the outflanking of intentional law. Any one of these claims might be thought to support a soft collectivism: that is, a position that is collectivistic so far as it makes intentional psychology somewhat less important than it may have seemed but that is consistent, nevertheless, with the soundness of intentional psychology. I shall mention six such claims, many of which are quite plausible theses. The claims address a somewhat different question from that to which hard collectivism provides an answer.

The first question that is important to distinguish from the hard collectivism issue is the question that divides those who are well described as atomists and holists: the question as to whether the individual agent noncausally depends on relations with other people for the appearance of distinctive human capacities (Pettit, 1993). Holists maintain that individual people are dependent on one another for the possession of distinctive human capacities: say, for the capacity to think. However, this belief need not lead them to hold that people cannot therefore have the autonomy of subjects who act more or less rationally in the light of more or less rationally held beliefs and desires. Intentional psychology is silent on the question of whether a capacity like that of thought requires communal resources. The holist assertion that thought does

require those resources cannot, therefore, undermine that psychology.

The second issue that is distinct from the issue that divides individualists and hard collectivists is whether groups can ever have a more or less autonomous status as corporate agents or legal persons or whether 'singularists' are right to say that the only real agents are individuals. The question is not whether any groups can perform as if they were individual agents or persons, which corporations and churches and states clearly can. Rather it is whether they have such a unity as agents that in practice the only way to understand and interact with them properly is to abstract from their particular members, with their particular attitudes, and treat them as agents with minds of their own: agents with judgments and preferences that form and update, and ultimately shape behavior, on a pattern is not discernible just on the basis of the corresponding attitudes of their members.

There have been thinkers who defend the reality of groups on in a collectivist manner, postulating the appearance of a group mind or spirit that displaces the minds of individual members (Runciman, 1997). However, a commitment to group agents of the kind described need not involve collectivism. A recent theory supports such a commitment, not on collectivistic grounds, but on grounds related to problems in the aggregation of individual attitudes into group attitudes (List and Pettit, 2011). The reason why group agents enjoy a certain autonomy, on this approach, is that it is effectively impossible for a group to be sure of displaying a sensitivity to rational constraints like consistency – a precondition for performing like an individual person – while allowing its particular attitudes to be determined in systematic response to the corresponding attitudes of individuals. This shows that it is possible to reject a singularism about group agents, as it is possible to reject atomism about people in society, without rejecting individualism.

The third question that must be distinguished from the hard collectivism issue has come to the fore in recent thought. Let us agree that people intentionally or nonintentionally produce – and reproduce – a variety of social entities by the patterns manifested in their attitudes and actions. They constitute social groups and instrumentalities, and they constitute the social properties that attach to certain individuals: the status enjoyed by this person, the power enjoyed by that. Here now is a question raised by such entities. Do the entities exercise a reciprocal influence on individual agents? Do they serve to determine, and indeed rationally determine, the opportunities, the motives and the perceptions of those agents, and thereby shape their further intentional responses? There are some who think, or who think certain individualists have to think, that the answer to this question is, no (Ruben, 1985). Those who defend an affirmative answer, therefore, will appear in the guise of collectivists. This means, in effect, that most contemporary social theorists will be given a collectivist cast (Giddens, 1976; Coleman, 1990).

The affirmative answer to this question is surely the correct one; social entities exercise a reciprocal influence on agents, at least so far as agents come to form beliefs and desires that involve those entities in their contents. Admitting the reciprocal influence of social entities in this manner does not in any way threaten the standing of our intentional psychology and does not involve a commitment to hard collectivism. I may be influenced by the objects in my social world, as I am influenced by the objects in my physical milieu, coming to form beliefs and desires in respect of them, but this does nothing to compromise my capacity as an intentional subject.

A fourth proposition that is collectivistic in spirit but not damaging to intentional psychology is a thesis of revisability. It is the thesis that the regularities identified in social science often challenge intentional psychology in the sense of pointing us toward unsuspected disturbing factors. Like the holistic and reciprocity doctrines, this revisability thesis is perfectly plausible. Consider the sort of regularity that much of Goffman's work is given to supporting: that people, in his language, are extremely loath to break frame, that they readily establish a set of shared assumptions about what is say-able and do-able in any interaction, and that they generally conform to those assumptions, even at the cost of considerable frustration of their other desires or ideals (Goffman, 1975). Anyone who has read the work of Goffman is likely to conclude, quite reasonably, that here we have been alerted to a factor that is often going to disturb people's intentional performance. The work of such social scientists bears out the truth of the revisability thesis ascribed to collectivists, that the identification of social regularities is likely to point us to conditions that disturb the operation or revelation of people's intentional processes, and in that sense that it is likely to affect our intentional psychology.

Although the revisability thesis is plausible, it does not serve to displace intentional psychology in a collectivist manner. The frame law used in illustration leaves intentional psychology fundamentally intact. Intentional psychology is an open-ended practice; it remains possible at any stage for its practitioners – who are of course also its subjects – to revise their conception of favorable conditions. If social science can interact with intentional psychology to force such revisions, in particular revisions that can be internalized by participants in their practice, then that does not involve any displacement of intentional psychology; on the contrary, it serves as a way of enriching the practice. Consider the effect of the discovery in optics that a rotating disc with a certain black–white pattern looks to be colored in different ways at different speeds. This does not undermine the intentional-psychological story of color perception but simply points us to a perturbing factor – rotation – that generally goes unnoticed but that is of a kind with factors – say, to do with lighting conditions – that are commonly recognized. A similar gloss will apply to the deliverances of social science, under the revisability thesis.

So much for the antiatomism and antisingularism, the reciprocity, and the revisability claims, which should be distinguished from hard collectivism. The fifth claim that should equally be distinguished from it is a thesis about the dispensability of individual contributions to social life, the sixth a claim about the inevitability of those contributions.

The dispensability thesis would say that while any socially significant event is going to come about because of the actions of this or that individual or set of individuals, still no individual makes an indispensable contribution. Had that individual not existed or not acted appropriately, still the phenomenon in question would have occurred. It is either the case (1) that the individual's contribution was not a necessary part of the total cause of the phenomenon or (2) that in the absence of that individual some other agent would have taken its place.

Durkheim was motivated by the existence of certain social constancies – the suicide rate, the divorce rate, and the like – to defend a thesis of type (1). The fact that these constancies survive variation in the individuals and the mentalities of the individuals involved shows that no one individual contribution is a necessary part of the relevant total cause. In defending this sort of dispensability claim, Durkheim was doing nothing to displace intentional psychology, so that the claim could be defended equally well by an individualist. The social constancies in which he was interested are characterized at such a high level that the absence of one individual contribution would not make a difference to the obtaining of the constancy. An artifact of aggregation and abstraction accounts for the dispensability of individual contributions, not any radical questioning of intentional psychology.

What of the other sort of dispensability thesis: the type (2) thesis that even with social phenomena that do actually depend on particular individuals – say, something like a political revolution – that phenomenon would still have occurred even in the absence of a relevant contributing party; it would still have occurred, because there would have been someone else available to take the vacated place? This type of claim is not associated with Durkheim particularly but is to be found in other, more historically oriented traditions of social science. The main source is the Marxist tradition and here Engels is quoted as making a telling remark about Napoleon Bonaparte "That such a man, and precisely this man, arises at a determined period and in a given country is naturally pure chance. But, lacking Napoleon, another man would have filled his place" (Sartre, 1963). Is this sort of dispensability thesis inimical to our intentional psychology? I think that it is not inimical, although I doubt that it is generally true (James, 1984). All that is required for it to be the case that an individual's contribution is dispensable in this sense is that a number of individuals have the capacity and motivation required to make the sort of contribution involved but that at most one individual can have the opportunity. To think that this was true of all individually necessary contributions to socially significant phenomena might be dogmatic, but it would not involve rejecting intentional psychology.

The sixth and last sort of thesis that should be distinguished from hard collectivism fits better with less empirical parts of Durkheim's work than his study of suicide: for example, with his analysis of the division of labor characteristic of our sort of society. I describe it as an inevitability thesis, as distinct from a dispensability thesis. What it says is that various features of social life limit the opportunities available to individual agents – they are structural constraints on feasible optio.ns – in such a way that it is inevitable that agents will act so as to sustain certain social constancies: "In an extreme version this would mean that the constraints jointly have the effect of cutting down the feasible set to a single point; in a weaker and more plausible version that the constraints define a set which is so small that the formal freedom of choice within the set does not amount to much" (Elster, 1979). This could be what collectivists have in mind, at least some of the time, when they denigrate the place of the intentional subject. Certainly it is a thesis that many social scientists defend.

The inevitability thesis, even in the weaker version, is generally unsound. However, that is beside the point in our present discussion. More important, it does no more than the dispensability thesis to undermine intentional psychology. It just might be the case, as the inevitability thesis has it, that our opportunities are tailored to the production of certain social constancies: that we are so limited in our range of options that it is inevitable we will act so as to sustain such constancies. Even if it were true, that would cast no serious doubt on the soundness of intentional psychology or on our status as autonomous subjects. It would not mean that we individual subjects were compromised by social laws in a manner that undermined our view of ourselves as intentional subjects. Our intentional psychology represents us as more or less rational subjects but it says nothing on the range of opportunities that are actually available to us as agents.

It may come as a surprise that hard collectivism is not entailed by the inevitability thesis or the dispensability thesis. Many self-described individualists would certainly want to deny the general truth of such propositions. Even if that is so, the matters in question do not go to the heart of the issue between individualism and collectivism: they do not have an intimate bearing on the status of our intentional psychology. They support a soft sort of collectivism but not the hard kind that would provide a really significant challenge to our self-image.

Abstract

Philosophical dimensions of the distinction between individuals and collectives include the problem of universals (how are similarities among members of collectives to be explained?), of emergent properties (do collectives have properties that are different from those of their members?), and of internal and external relations (are the properties of individuals brought into being by membership of collectives?). In political philosophy the problem of the authority of the state as a collective led to accounts by Hobbes, Locke, and Rousseau in terms of a (mythical) moment of a social contract between members to create a sovereign. By contrast Vico saw the state as a development of the existing social structures of families. Utilitarians assumed, problematically, that properties of groups of people were merely aggregates of attributes of individuals. Mill defended a radical distinction between individual and collective as the ground of political freedom. Hegel and Marx made collectives fundamental. Individuals acquired different attributes by virtues of membership of social aggregates which changed as the history of humanity unfolded. Durkheim too assumed that there were social facts not reducible to attributes of individuals. Sociology, as the study of collectives, can focus on attributes of individual members (idiography) or attributes of groups (nomothetic research). The debates around ontological and methodological individualism continue still.

The concepts 'individual' and 'society' are intimately related. Societies, whatever else they may have been thought to be, are collections or groups of individuals. Many philosophers and psychologists have thought that individuals only took on the characters they did by virtue of the influence of the society in which they grew up. But which had priority? Which was the cause and which the effect? The problem of how the concepts of individual and society are related has been part of a more extensive philosophical debate on the nature of classes and their relations with their own individual members. Some have argued that we can dispense with class concepts in favor of ones referring only to individuals, others that any such attempt will necessarily fail.

Philosophical Aspects of the Individual/Society Contrast

Kinds of Groups

The problem of how to interpret the concepts of individual person and social collective is embedded in a more ample philosophical issue, the general question of how to understand the contrast between individuals and groups and the interrelations between them. There are two main kinds of collectives or groups that are of relevance to social science. There are taxonomic groups in which the members share some set of qualifying properties but may have no real relations with one another. Two people may be members of an ethnic minority solely on the basis of their mother tongue, or their religious affiliation. This concept of a collective is particularly appropriate to the study of groupings like social classes. Then there are structured groups like families or institutions, the members of which may be biologically or socially related to one another. In structured groups members are usually different from one another with respect to group membership. Mum and Dad are members of the nuclear family just insofar as one is female and the other male. In recent sociology and social psychology such groups have been analyzed by the use of the concept of role. It seems particularly appropriate to the study of institutions and teams.

The Related Problem of Universals

Philosophical problems associated with taxonomic groups have a history that reaches back through Medieval attempts to deal with the problem of universals into antiquity and the Platonic forms. How could one account for the fact that many individual entities were the same color? Or the same shape? According to the Ancient Greek philosophers this fact had to be explained by some version of the form and matter distinction. Clearly similar things shared a common form. How did that form exist? Plato built his account on the principle that the property displayed by each individual entity was a realization in the material world of a form that transcended it. The Platonic account has often been rejected. In the later Middle Ages, William of Ockham argued that the only common element in a group of things of the same color, for example, is the use of the same *word* to describe each of them.

Emergent Properties

The idea that collectives are somehow more than the sum of their members has persisted, albeit in rather different ways, down to the present day. The notion of an 'emergent property' has been coined to describe cases in which a collective of parts, say a brain composed of neurons, has a property, a capacity for thought, that is not possessed by any neuron taken singly. Emergent properties contrast with aggregative properties such as weight. Both brains and their component cells have weight. An important debate in social science centers on the issue of whether among the emergent properties of social structures are causal powers. Some have argued that agency is an attribute only of the human beings who create these structures.

Internal and External Relations

The third main issue concerning the relation between individuals and collectives is tied in with the distinction between internal and external relations. Two beings are internally related if their natures are partly or wholly determined by their standing in those relations. Marriage is an internal relation in that a person becomes a husband or a wife by virtue of being related by marriage to someone else. Spatial relations are commonly cited as examples of external relations between people, though they may not be for material things in general. The general question is whether people are the products of the societies in which they have a place or are the societies' products of the activities of people? Contemporary structuration theory takes a middle way, seeing people as shaped by their social relations and in turn, in their subsequent ways of living, recreating those social relations, albeit imperfectly.

Hobbes and Locke: The Genesis of the Sovereign

Leviathan: Individuals Covenant to Maintain a Sovereign

In Protestant Europe the individualism of the renaissance soon evolved into the idea of the state as a corporation of citizens. What sort of collective could such a corporation be? Where is the sovereign to be found in such a picture of the state? From what source does the state derive authority, when the Divine Right of monarchs is no longer accepted? The overt philosophical problem, which is to ask in what way a corporation exists other than as an aggregate of its members, was displaced by the more pressing question of how a group could come to have an identity to which a citizen owed a duty of obedience. The social contract, an agreement to give up some of one's individual freedoms for the benefits of civil society, in particular personal security, was invoked by Hobbes, Locke, and later Rousseau as a necessary precondition for a social order to arise out of individual aspirations and intentions.

This was the moment at which the collective emerged from the aggregate of individuals. It was also the ground of the state's authority. Both aspects of the social contract appear very clearly in Hobbes's *Leviathan* of 1651.

> [the agreement that creates civil government] is more than Consent or Concord; it is a real Unity of them all, in one and the same Person [the Sovereign], made by Covenant of every man with every man ... [This creates a Commonwealth, the essence of which is] One Person, of whose Acts a great Multitude, by mutual Covenants one with another, have made themselves everyone the Author, to the end he may use the strength and means of them all, as he shall think expedient, for their Peace and Common Defence. (Hobbes 1651, Part 2, Chap. 17)

Yet it is not the collective that is sovereign, since the purpose of the creation of the unity is the delegation of powers to an individual. Each person is the 'author' of the acts of whosoever is the sovereign.

The General Will

Rousseau, writing a century later, dispensed with the sovereign as such. Here we have the submergence of the individual in the collective.

> Each one of us puts into the community his person and all his powers under the supreme direction of the general will; and as a body we incorporate every member as an indivisible part of the whole. (Rousseau 1764 [1968], Book I, Chap. 6)

Nevertheless he insisted that the legislative role of the social group was necessarily distinct from the power to execute the general will.

The metaphysical question of the kind of reality that the collective or group might have, by way of contrast with that of the members taken individually, is not directly addressed by these authors. For instance no one in the high era of the social contract paused to ask for the criteria of identity and individuality of a society, nation, or institution. Nor is the issue of the status of emergent properties raised so far as I know. It is certainly implicit in Rousseau's version of the social contract in that the 'general will' of the collective is explicitly distinguished from the aggregate of personal wishes and intentions, the 'will of all.'

Vico and the Role of Unintended Consequences

The question of how a group of individuals can come to have a collective identity troubled Giambattista Vico (1668–1774). Unlike his distinguished predecessor, Machiavelli, he did not see the collective as the product of the power and will of the sovereign. He remarks that

> It is true that men have themselves made this world of nations …. But this world, without doubt, has issued from a mind often diverse, at times quite contrary, and always superior to the particular ends that men had proposed to themselves; which narrow ends, made means to serve wider ends, it has always employed to preserve the human race upon this earth. (Vico 1725, p. 1108)

How is this possible? How can one account for the transition from anarchy to the institutions of the state? It cannot be by the accidental coordination of individual motivated acts. The superior 'mind' Providence employs individual intentions to bring about social order.

Providence is not God, but should be interpreted, I believe, as a metaphor for the flux of unintended consequences of individual acts. There is no need for a social contract to bring the conditions of order into being in Vico's view. Social order comes to be because the conditions for its emergence are already in existence.

> Yet chance did not divert them nor fate force them out of this natural order. For at the point when the commonwealths were to spring forth, the matter was all prepared and ready to receive the form, and there came forth the commonwealths composed of body and mind. The prepared materials were these men's own religions, their own languages, their own lands, their own nuptuals, their own names, their own arms ... and because these things were their own they were completely free and therefore constitutive of true commonwealths …. The fathers at this juncture, by uniting themselves in an order, came to produce the sovereign civil power, just as in the state of nature they had held the family powers …. (Vico 1725, p. 630)

By bringing about the birth of families, each with its own language and rules of life, Providence had at the same time brought into being the natural law to be used in the management of commonwealths.

The identity of a nation was identical with the identity of a family, only writ large. Vico's collectives were structural not taxonomic.

The Problematic Status of Collectives

Vico's account of the genesis of the state neatly avoids the issue of how individuals can jointly constitute a collective entity the properties of which are not just aggregates of the properties of individuals. He denies individual intentions an explicit role and at the same time traces the means of maintaining institutions back to simpler institutions in which individual intentions directly create social order. In essence Vico assumes the native character of institutions. They are just there.

Utilitarians and Collectivists

Individuals and Freedom

The Utilitarians, Jeremy Bentham (1789), and the Mills, father and son, had no difficulty with the concept of collectives of human beings, for rather the opposite reason from Vico. For them the properties of groups were just aggregates of the attributes of the individual members. The happiness of all was the arithmetical sum of the happinesses of each. The Utilitarian account of the relation between individual and collective is sometimes used to illustrate the fallacy of composition. To infer from the fact that each of the 20 soldiers in a platoon is six feet in height that the platoon is 120 feet high is an obvious fallacy. Is it not equally fallacious to give a measure of the happiness of a society as the sum of the happinesses of individual members?

John Stuart Mill's (1859) *On Liberty* presupposes a sharp distinction between individual and society, at least when 'society' takes the form of government, public opinion and so on. He argued for the fundamental moral propriety of resisting those who claim to be the voice of the mass. Freedom and individuality are more or less the same thing for Mill. There is a contrast for him between the self-subsisting power of the individual to resist and the power of the state to coerce.

We would now tackle the problem of picking out which properties could be aggregated and which could not by invoking the idea of an emergent property, and using examples of the difference between the properties of constituent cells and the organs of which they are components to illustrate the point. What could one make of the idea of a group happiness as an emergent property of the individual activities of the members of a society?

Collectives and Mass Societies

Running more or less parallel to Mill's individualistic utilitarianism, Hegelian idealism presented a very different picture. History is a collective progress since the world spirit, *Geist*, is embodied in the human race as material beings, more or less as individual minds are embodied in individual bodies. All relations between all beings whatsoever are internal and constitutive. As the realization of the one World Spirit human beings have a unity as a kind of supra-individual.

Marx and Durkheim

Marx's sociology, the structure of which is drawn more or less directly from Hegel's metaphysics, pitted class against class in a dialectic of contradictory interests (Marx 1867 [1965]). The this-ness of individuals gave way to the individual class member as relevant to sociology only as the vehicle for the necessary attributes of class membership. Borrowing from Hegelian Idealism, Marxian 'Man' was the nexus of internal relations, the relations of the social necessities of certain means of the production of the material necessities of life. However, Marx's two main social classes were taxonomic, in the sense I have defined above. To be a member of the working class or of the bourgeoisie was to exemplify a certain set of attributes, though those attributes were possessed by virtue of standing in certain internal relations to other people.

Durkheim's plea for sociology as the science of 'social facts' comes close to Marx's unpsychological sociology insofar as Durkheim's social facts are attributes of groups. In his *Elementary Forms of the Religious Life* (Durkheim 1895 [1982]), the ceremonies of the Native Australians are to be interpreted as presentations of collective facts about the local social order through participation in which loyalty and commitment to that order are renewed. Again the collective is thought of in aggregational rather than structural terms.

What Sort of Science Is Sociology?

Windelband and the Nomothetic/Idiographic Distinction

The individual/collective issue appears not only in metaphysics and social theory, but in methodology as well. That there are two kinds of human sciences was the claim of Windelband (1894 [1998]). There are studies of individuals as such, an idiographic science. There are studies of people in groups or collectives, a nomothetic science. The analogue of a law of nature had no place in idiographic science while, perhaps with the help of statistical analysis, it could have a place in nomothetic science. This distinction is related to but not identical to that between two kinds of empirical enquiry. There is the intensive design, the study of a group by the study of a typical member and there is the extensive design, the aggregation of information about the members of a population into a statement about the population as a whole. The results of studies based on the extensive design will tend to ignore emergent properties, since they are not aggregates of the properties of individuals.

The Reduction of Collectives to Individuals

In the twentieth century the issue has surfaced again, this time in the guise of the problem of explanation. Are the collective aspects of human societies to be accounted for as just patterns of the unintended consequences of individual actions according to individual intentions? Or are they mass social effects of mass social causes? If we take the former view, explanations of mass

phenomena must be sought not in other mass phenomena, but in the intentions of individual actors as they ramify through a population and interact with the intentions of other actors. This proposal has been called 'methodological individualism.' It has been revived by Popper (1961) and others. The idea is an old one. Adam Smith (1776) thought that individual choices in the marketplace 'added up' to the illusion of the 'hidden hand.' It had an important place in Menger's (1883 [1981]) advocacy of microeconomics, the study of the grounds of individual acts of choice as opposed to statistical analyses of vast masses of data. It cannot be a wholly individualistic story since some reference to structure seems to be essential to understand how individual actions could aggregate into something that could be perceived as orderly.

Adam Smith (1776) and Carl Menger (1883 [1981]) did not feel the need to offer arguments for methodological individualism, since each thought he had shown its methodological advantages. In the 1950s a more recognizably philosophical debate began, forcing the positions to be more clearly differentiated and the arguments' pro and con more carefully formulated. Three lines of argument in favor of collectivism can be discerned. A metaphysical argument emerged to the effect that individuals are simply products of social processes (Lukes 1973). Then there was an epistemological argument that the tactic of studying only individuals will not allow the recovery of properties of groups. Finally there was a conceptual argument that collectivist concepts such as 'nation' or 'army' cannot be replaced by individualistic ones like 'citizen' and 'soldier' with preservation of meaning.

I think it is fair to say that the issue has not been resolved to anyone's entire satisfaction. The degree to which one sees the ideal form for a society along the polar contrast between collectivist and individualist is not just a question of one's political or religious affiliations. It is also a matter of how far one sees oneself as a product of ready-made social orders, and how far one thinks of oneself as a crusader against the tyranny of the majority.

Abstract

In this article the criteria for establishing language families are reviewed, and are then applied to a diagnostic set of morphological and phonological data from the Indo-European family of languages. Each of the 11 subgroups of attested Indo-European languages is outlined, with essential dates and earliest monuments mentioned for each group. An outline of the phonological system of the protolanguage is provided, as well as sample information on its morphological and syntactic systems.

Language Families

Inheritance

Before we begin our discussion of the Indo-European (IE) family of languages, we should make explicit what exactly we mean by the term 'language family.' The term 'language family' is used in linguistics to characterize a genealogical model of the relationship between languages. A 'family' of languages is a set of languages which derives from a common ancestor or 'parent' language, e.g., the IE family of languages consists of the 'daughter' languages Greek, Latin, Sanskrit etc., all of which developed out of the Proto-Indo-European (PIE) ancestor. Languages that have a common ancestor can be shown to share common traits, which identify them as members of the same family.

Curiously, the genealogical analogy extends only as far as the node of the single parent, usually the 'mother' language. Under normal circumstances of language evolution, there is only one parent. When there is more than one parent present, we are dealing with a 'creole' situation, which is not generally considered to be normal language evolution. Under such circumstances speakers may cobble a language together using parts from two existing languages that they know (Dixon, 1997: 13). The creole model is particularly useful when linguistic families exhibit scant evidence for a chronologically deep reconstruction.

The notion of the language family is usually restricted to units comprising agreed-upon languages and language subgroups. Beyond the family, there is the 'phylum.' A phylum is a grouping of languages, which is much more speculative than is a family: a phylum is a more remote level of grouping, where a clear ancestor is not known. The term 'macro-phylum' is used for even less certain groupings of languages.

For example, one can find the term 'Australian family' (of Aboriginal languages), even though there is no clear parent language and it is not even clear that the languages in this 'family' are related to each other. For this grouping the term 'phylum' or 'macro-phylum' would be a better choice.

Evidence

The notion of a language family is founded on the idea that two or more languages may display a noticeable similarity to each other. They may share common elements of lexicon (vocabulary), phonology (sound patterns), and morphology (word structure) and those similarities may be an indication that the languages are descended from a common ancestor. If the shared features are not due to chance, to borrowing through contact or to universal properties of language in general, then the languages in question have most likely inherited these features from a common source, a mother language. It follows from this that the languages are in the same family.

The relationships of the members of a language family are typically represented in *family tree* diagrams such as the one below.

We should point out that family tree diagrams are much more complicated as they typically have a number of subgroupings. Continuous branching is the norm, with subfamilies continuing to split until every node on the tree ends with a specific language. It is assumed that features which are shared via contact have been isolated and eliminated from genealogical consideration (fully articulated trees of the IE family can be found in Baldi, 2002: 22; Fortson, 2004: 10).

With the foregoing discussion in mind, let's return to the question: how do we know that languages are related to each other, that they stem from a common ancestor? In other words,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52046-7

how do we know that they are in the same family? We can start by reviewing some morphological data from several languages that share some similarities that we want to explain. Remember, this is only one part of the proof of genealogical relatedness. Similar types of arguments can be made by comparing phonology and syntax.

Linguists know from over two hundred years of scientific study that while languages freely borrow vocabulary it is less frequent that they borrow elements of grammar or word formation. It would be unlikely, for example, for a language to borrow the plural ending on nouns, especially a rare or irregular one, like the *-en* on *oxen*, or the *-ren* on *children*, or a vowel-changing plural like that in *foot/feet*. Nor would we expect to find borrowed verbs of the form seen in *sing/sang*; or *bring/brought*. Each of these forms marks a highly specific lexical function and it would be very unusual for another language to borrow them.

The reason languages don't borrow these types of forms is that more general mechanisms already exist within each language that perform these functions, forming the plural of nouns and the past tense of verbs. Furthermore, specific endings such as *-ren* or *vowel change* are from a layer of exceptions that exist in languages and are unique to the words mentioned. For example, the word *foot* has a plural form, *feet*. This type of plural in English is restricted to a few nouns such as *goose/geese*, *tooth/teeth*, *mouse/mice*, *louse/lice*, and so on. If English were to borrow or coin a word *schnub*, meaning 'a box full of foxtails,' the plural of this word would no doubt be *schnubs*, not ***schnuben*,***schnubren*, or ***schnub-schnibrin*.

We can illustrate further with a less abstract example. The verb to *sauté* is borrowed into English from French. The past tense of *sauté* in English is formed by adding the normal past tense marker *-ed*, *sautéed*. In other words, the past tense is formed by using the English ending *-ed*, not the French past tense formation (which would be **I have sauté*), or some irregular English marker such as *sauté/*seuté*, which would be like *fall/fell*. Similarly again with plurals: *typhoon* is borrowed into English from Chinese. If there is more than one of them, they are *typhoons*. English uses its most common plural and doesn't follow the Chinese pattern (which would be *typhoon*), or some other English plural marker such as ***typhoonen*, ***typhoonren*, or ***typhoon-typhin*. (Note: Possible but nonoccurring words are marked with ** in this article).

But this is all negative evidence – what we wouldn't expect to find, not what we would expect to find, if two languages were related. Let's consider some data from German and English, two well-known European languages that we already know to be in a genealogical relationship. Based on our observations of living languages, we would not expect to find a set of irregular adjectives to be borrowed from one language to the other, but yet we find a near-perfect match between two such forms in both English and German, viz., Eng. *good/better/best* and *much/more/most* paralleled by Germ. *gut/besser/best* and (*viel*)*/mehr/meist*. Each is an exception to the general rule of adjectival comparison in present-day English and German (i.e., add the suffix *-er* and *-est* on the base of an adjective: *tall*, *taller*, *tallest*; *dunkel*, *dunkler*, *dunklest*). This would be a most unusual borrowing; indeed, the only practical explanation for this shared similarity is that the two languages inherited the pattern from some earlier stage in their history, when they were undifferentiated:

Here is a summary of some formations shared by English and German, which can only be explained by common inheritance:

German has a (rare) plural suffix in *-s*, which matches the one in English (German: *Schmidt/Schmidts* = English: *Smith/the Smiths*).

In German, *-en* is found in plural formations such as the word for *woman* (*Frau/Frauen*). It is the same as that seen in the plural of the English *ox/oxen*.

In German, there is a vowel-changing plural in *Fuss/Füsse* (pronounced *foos/fees-uh*), which is paralleled exactly by the English *foot/feet*.

In German, the irregular comparative formation *gut/besser/best* is a perfect match to the English *good/better/best* and the German *viel/mehr/meist* is a partial match (the latter two words) with the English *much/more/most*.

In German, the verbal forms *bringen/brachte* match the English *bring/brought*, and the German *singen/sang/*(*ge-*)*sung*(*-en*) matches the English *sing/sang/sung*.

The presence of such a high degree of similarity in these specific parts of German and English is a robust indicator that the two languages are related and that they have inherited features from some common ancestor. The common ancestor in this case is Proto-West-Germanic.

The Comparative Method

In addition to the similarities which are made obvious by morphological comparison, we also evaluate the data according to the comparative method, which is a method used by linguists to test the phonology for patterns of similarity and consistency among matching segments. We have already seen how morphological data are used to establish filiation between languages.

Consider the following data, from four West-Germanic languages and Latin:

English	*Dutch*	*Latin*	*Yiddish*	*Old English*
mouse	muis	mūs	moyz	mūs
seven	zefen	septem	ziebn	seofon
wind	wind	ventus	vint	wind
goose	gans	(h)ānser	gandz	gōs
winter	winter	XXX	vinter	winter
goat	geit	haedus	XXX	gāt 'she-'goat'
wade	waden	vādere 'to go'	XXX	wadan
whore	hoer	cārus 'dear'	hor	hore
mother	moeder	māter	muter	mōdor
six	sechs	sex	zeks	siex
sister	zuster	soror	shvester	sweoster

XXX indicates that a cognate is lacking.

The overall composition of these words, in effect, satisfies the morphological criterion that the vocabulary must bear some similarity to each other. Our basic intuition about these words is that the members of each line are, in a sense, 'the same word.' However, making this assertion and proving it are two different things. To prove it, we must establish that there is a systematicity to the phonological patterns that we claim to have found.

That systematicity is to be found in the *regularity* with which one sound represents a parallel sound in another language. For example, the *m-* in 'mouse' is consistent in the initial position in our chart ('mouse,' 'mother'), and the same is true of the *-n-* in 'wind' and the *-r-* in 'whore.' Note also that the initial *g-* in 'goose' and 'goat' are matched by an *h-* in Latin (the initial *h-* of (*h*)*anser* is optionally written, showing the weak articulation of the *h-*). The medial *-d-* of 'wade' is a match. Note that the vowels seem to have a less-than-regular pattern, at least when compared to the consonants. But this is an illusion: in fact, the vowels show as much systematic correspondence as do the consonants, though the demonstration of these correspondences would take us way beyond the purposes of this survey. What we should stress, however, is that sounds need not be identical, or even phonetically similar, in order to fit into a sound correspondence. What matters is that they be systematic in their correspondences. An extreme, but instructive example of this is to be found in Armenian *erk-*, which systematically continues *dw-*, even though the clusters are phonetically very different. The somewhat problematic final *-n* in 'seven' can easily be shown to derive from an earlier *–*m*. The final *-n* in 'wade' appears only in two of the five words, where it is a morphological marker indicating "infinitive,' and hence is not a part of the phonological equation, and not subject to regularity. The final *-d* in 'wind' is matched by two *t*'s in Latin and Yiddish, and by a final *-d* in Dutch and Old English. All these can be traced back to a final *–*t*, with Dutch and Old English giving way to a forward (progressive) assimilation of voice in the combination *-nt*, which results in *-nd*. The *g-* of 'goose' and 'goat' is consistently derived from an earlier reconstructed **gh-*, with the normal outcome of this sound being *g-* in Germanic, and *h-* in Latin.

With the exception of the words marked with XXX, where there is no cognate form, we can readily see that there is a systematicity of correspondence in these data. That is, wherever we find a *g-* in the initial position in English, we are sure to find an *h-* in Latin. And so it is with all the other words in Germanic which begin with *g-*, such as 'guest' (Eng. *guest* = Lat. *hostis*). Note once again that we are not claiming that the sounds must be the same from language to language, but only that they match, or correspond. That is, if there is a sound X in environment A in Language 1, then there will consistently be a sound Y in environment A in Language 2 if the languages are genealogically related (Campbell, 2004).

The IE Family of Languages

By the term 'Indo-European' we are speaking of a set of genealogically related languages which, by the second millennium, were written and/or spoken over a large part of Europe and parts of India, stretching from the Indian subcontinent in the east and Europe in the west at the time of their identification as a family in the eighteenth and nineteenth centuries. Of course, modern discoveries such as Anatolian (discovered in modern Turkey) and Tocharian (found in western China), as well as post-Columbian colonial expansions, now suggest a different name, but the original 'Indo-European' (and its German equivalent *Indogermanisch*) has stuck through the centuries.

Thus, though the term is in origin a geographical one, the name *Indo-European* is primarily linguistic, referring as it does to linguistic branches of the language family, such as the 'Italic branch' or the 'Germanic languages.'

The dating and location of the protolanguage from which all the IE languages have descended are controversial but the most widely held opinion among specialists puts the protolanguage in the area of the Pontic-Caspian steppes north of the Black and Caspian Seas at around 3500 BCE. Around this time the protolanguage began to diversify into the descendant subgroups through a number of phases and stages. Proposals have been made for a later date (*c*2500 BCE), also in the steppes, and for a much-earlier beginning for the protolanguage, from *c*7000–10 000 BCE, in what is now modern Turkey. Still other proposals project the protolanguage back to *c*12 000 BCE, for the macro-phylum called *Nostratic*, which included, besides IE, the Semitic, Caucasian, Uralic, Altaic, and Dravidian families. Most scholars are not persuaded by either of the earlier dates or at least by the availability of methodology which can take us back that far. This is the position that we adopt in this article.

In comparison with some of the other 250–300 language families of the world, the IE family is relatively small. It contains about 140 languages (many extinct), more than 90 of which belong to the Indo-Iranian family. These 140 or so languages are classified into 11 subgroups, namely Anatolian, Tocharian, Indo-Iranian, Baltic, Slavic, Armenian, Albanian, Germanic, Celtic, Italic, and Hellenic (Mallory, 1989).

By contrast, the Austronesian language family (Pacific) has some 800 languages in a large number of subgroups, and the Bantu family (Africa) has as many as 400 languages. Of course, it is important to distinguish the number of languages in a family from the number of speakers, or their social/geopolitical importance. By these latter criteria the IE family, specifically through global languages such as French, Spanish, and especially English, has an almost unique standing among the language families of the world.

When we say that such and such a word is IE, it means that we are claiming that the word can be traced all the way back to PIE and that it has evolved in the daughter languages as a descendant of PIE. When we claim that a word is Germanic (or Baltic, etc.), we are claiming that the word is only found in the Germanic subfamily more or less in that form. If we say that a word has been borrowed from A into B, we are saying that the word is not original in B.

We now discuss each IE subgroup and the dates of its most important linguistic monuments.

The IE Subgroups

Anatolian. Completely extinct, the Anatolian languages were unknown until archaeological excavations in Boğazköy,

Turkey, in the early twentieth century uncovered the royal archives of the ancient Hittite city of Hattušaš. The original trove of about 10 000 clay tablets (now numbering 25 000), dating from the seventeenth to the thirteenth centuries BCE, was deciphered from its cuneiform script and shown to be representing an IE language now called Hittite. Other languages were also represented in the tablets, both IE (e.g., Palaic and Luwian) and non-IE (e.g., Sumerian and Akkadian). The main language of the Hattušaš materials, however, was Cuneiform Hittite, the chief representative of the Anatolian branch. Other Anatolian languages which have been uncovered and classified since that time are Palaic, Hieroglyphic and Cuneiform Luwian (and its offshoot Lycian), Carian, and some other fragmentary languages.

Indo-Iranian. This subgroup contains two closely related subdivisions, namely Indic (also known as Indo-Aryan) and Iranian. Because of the extremely early dates of attestation for the oldest languages of Indo-Iranian, especially Sanskrit, and their generally conservative (preserving many features of the protolanguage) character, these languages have figured heavily in our understanding of the protolanguage and of the IE language family.

Indic (sometimes called Indo-Aryan). The languages of the Indic group are classified into three historical periods, namely Old Indic (1500–600 BCE), Middle Indic (600 BCE–CE 1000), and Modern Indic (since CE 1000). The most ancient language is Vedic, an archaic form of Sanskrit whose oldest documents are usually dated to about 1200–1000 BCE. A closely related form of Vedic is Classical Sanskrit (*c*500 BCE). The oldest Middle Indic texts are in Pāli (sixth to fifth century BCE), followed by the Aśoka inscriptions (*c*250 BCE) and some Jainist religious writings from about the same period. Modern Indic is one of the largest and most heterogeneous of the IE subgroups, with perhaps as many as 90 different languages. Among the best known of them are Hindi/Urdu, (Hindi is written in the [Hindu] *devanāgarī* script, while Urdu is written in the [Moslem] Arabic script, though the languages are essentially the same), Marathi, Punjabi, and Gujarati. It should be noted that the majority of the modern Indic languages derive from the *Prakrits*, which are spoken varieties of Indo-Iranian that must be kept distinct from the written *Sanskrit*, which was used for religious purposes.

Iranian. Ancient Iranian has two important representatives of IE. The first of these is Avestan (with its oldest variety preserved in the Gāthās), dating from about 600 BCE, possibly earlier. The second important member of Ancient Iranian is Old Persian, which may date to as early as 500 BCE. Modern descendants of Iranian are, among others, Modern Persian (Fārsi), Pashto, and Kurdish.

Greek. The Greek branch contains some of the oldest testaments of the IE family. Attested in inscriptions from as early as the eighth century BCE, Greek also has textual monuments in the Homeric epics, *The Iliad* and *The Odyssey*, which may be as old as 800 BCE. Even older than these are the Linear B tablets from Crete, Pylos, and other ancient locales, which represent a form of Greek called Mycenaean and may date from as far back as the fourteenth century BCE.

Italic. The Italic subgroup of the IE consists of many genetically connected languages from ancient Italy that share certain distinctive characteristics. There are two main Italic subdivisions. The more important of the two, Latin–Faliscan, is represented chiefly by Latin, one of the most important IE languages and arguably the most important language in the development of Western Civilization. Latin is identifiable in some short inscriptions from the seventh century BCE. However, the first literary texts stem from the third century BCE. Faliscan is known only from inscriptions, the oldest of which dates to the early seventh century BCE. Latin survives in the form of the modern Romance languages that developed from spoken varieties of the language in various parts, at different times, and in social circumstances in the history of the Roman Empire and beyond. The best known of the Romance languages are Italian, French, Spanish, Portuguese, Catalan, and Rumanian; less well known are Dalmatian, Rhaeto-Romansch, Ladino, Sicilian, Sardinian, Occitan, and many other local and social varieties. The second Italic subdivision is called Sabellic or Sabellian, represented chiefly by the Oscan and Umbrian, which in the *Iguvine Tables* represents the only foundation ritual we possess in any IE language.

Germanic. The Germanic subgroup, which includes English among its members, is widespread geographically. The oldest attestations of Germanic are the Scandinavian Runic inscriptions, the oldest of which dates from the first century CE. The Germanic languages are conventionally separated into three geographic subdivisions.

The first, East Germanic, contains only a single well-attested language, Gothic, which died out, but traces of which were still found in Crimea in the sixteenth century. The second subdivision of Germanic is North Germanic, whose principal older representative is Old Icelandic from the ninth century, Modern North Germanic languages are Icelandic, Faroese, and Norwegian in one group, with Danish and Swedish in another. The final group, West Germanic, is the most expansive and internally diverse of the Germanic languages.

Five West-Germanic subgroups are recognizable:

Old High German, which descends into Middle High German and on to Modern German and Yiddish, a 'fusion' language based on three components, viz. (the dominant) Germanic, Semitic, and modern dialects such as those from Slavic (Katz, 2000: 496).

Old Saxon, which eventually develops into Low German.

Old Low Franconian, which evolves ultimately into Modern Dutch, Flemish, and Afrikaans.

Old Frisian, which becomes Modern Frisian.

Old English (Anglo-Saxon) develops through Middle English to Modern English, with great influence of French after the Battle of Hastings in CE 1066.

It should be noted that 'Modern English' is not a single language, meaning that it has many varieties, some profoundly different from each other. As the most important language in the world, from an economic and political point of view, English is the most commonly acquired second language. Because English is a second language for many, this leads to countless numbers of varieties of English that have developed in different locales around the world, many of them mutually unintelligible. By way of illustration, consider the profound differences among English spoken in Africa, India, Hong Kong, Australia, Ireland, and Scotland, to name just a few.

Celtic. The languages of the Celtic subgroup are divided into two main geographical sections, the Continental and the Insular. The Continental group, made up of Celtiberian [Hispano-Celtic], Lepontic, and Gaulish, is extinct. The oldest written material from the Continental group is from the sixth century BCE. The Insular Celtic languages appear somewhat later. Split into two groups, Goidelic and Brittanic (Brythonic), the Insular languages are first attested in some Ogham Irish inscriptions from around CE 300. The Goidelic group is made up of Irish, Scots Gaelic, and the extinct Manx. The Brittanic group comprises Welsh, the most robust of the modern Celtic languages, Breton, spoken in Brittany (France), and the extinct Cornish.

Tocharian. Discovered in archaeological excavations around the turn of the twentieth century in Chinese Turkestan (Xīnjiāng), the two varieties of Tocharian (usually called simply 'A' and 'B') can be called a significant find, in the sense that they had a serious impact on IE studies, mostly in the form of disputed phonological and morphological archaisms which they preserved, and thereby confirmed for the protolanguage. The documents of the languages, mostly religious and some commercial, are relatively late, stemming from the period around CE 500–700.

Baltic. The Baltic subgroup survives in two modern languages, Lithuanian and Latvian (Lettish), which together make up the East Baltic subdivision. Many other Baltic languages have become extinct, including a language called Old Prussian, which was spoken until the early eighteenth century and represents the West Baltic subdivision.

Slavic. The Slavic languages fall into three geographical subdivisions. The first, South Slavic, comprises Bulgarian, Macedonian, Serbian, Croatian, Slovenian, and the extinct Old Church Slavic, in which the bulk of the oldest (tenth century) Slavic materials are written. The second Slavic subdivision is West Slavic, which comprises Czech, Slovak, Polish, Kashubian, and some others. And finally there is East Slavic, made up of Russian, Ukrainian, and Belarusian.

Armenian. Armenian is first attested in religious documents and translations from the fifth century CE. It shows a great deal of influence from neighboring languages, including Greek, Arabic, Syriac, and Persian. Persian was such a strong influence that Armenian was, at first, misclassified as a dialect of Iranian. Armenian is written in a script developed for Classical Armenian in the fifth century.

Albanian. Unknown linguistically until the fifteenth century CE, Albanian shows a great deal of influence from neighboring languages such as Greek, Slavic, and Turkish, as well as from Latin. This made its identification as a branch of the IE family somewhat problematic when the IE languages were being classified in the nineteenth century. The first document in Albanian is a baptismal formula from the fifteenth century.

Fragmentary Languages

In addition to these 11 subgroups of IE languages, there are also a number of 'minor' languages which are known only from fragments, glosses, inscriptions, and other unpredictable sources. The IE character of some of these languages has been called into doubt, but scholars generally agree on the basic 'IE-ness' of the following languages: Ligurian (Mediterranean region), Lepontic (with possible Celtic affiliations), Sicel (Italic?), Thraco-Phrygian (Armenian and Albanian?), Illyrian (prevalent along the Dalmatian coast), Messapic (connected with Albanian or Italic?), and Venetic (probably connected with Italic). None of these languages exists in sufficient material detail to be of much help in the reconstruction of PIE.

Reconstruction

When we say that we are comfortable with such and such a reconstruction, or that the earlier form of a word or sound was x or y, what exactly are we saying? Our claim is that the protolanguage from which our attested languages have descended is not attested, but it is still discoverable, by reconstruction. Reconstruction is a method used in historical linguistics in which a hypothetical system of sounds or forms representing an earlier, nonextant state of a language (proto forms in a protolanguage) is established deductively from the attested sounds and forms of extant texts. The process of comparative reconstruction is dependent on good written records of several known related languages. In the case of IE, these written languages usually turn out to be Greek, Latin, and Sanskrit, whereas the role of Anatolian is still debated. When such records do not exist, as in many American Indian and African languages, it is still possible to hypothesize about the historical development of these languages by conjecturing about the structural regularities and irregularities of their contemporary states and deducing underlying forms which might reveal earlier states – a process of internal reconstruction (Crystal, 2007: 388–389). Reconstructed items in this article are marked with an *.

The Structure of PIE

Based on the intensive comparison of the IE languages, the IE protolanguage has been reconstructed in considerable detail. In this part of the article, we will identify many of the more prominent features of the protolanguage, concentrating on the phonology, morphology, and syntax.

Phonology

The following phonological system is one of many that have been reconstructed for PIE (for two current ones, see Szemerényi, 1996; Fortson, 2004: 48–62). This system is the least controversial in that it does not incorporate changes brought about by the 'glottalic theory' proposed by Gamkrelidze and Ivanov (1995), now largely discredited.

The phonological system represented in **Figure 1** is based on the comparative analysis of the daughter systems. Some of the sounds have continued to be controversial, such as the set of palatal stops, while most others are secure, being squarely based on the comparative method. This system is maximally balanced: that is, for every sound that occupies a given slot in the system, there is an opposing sound which anchors it. For example, there is a voiceless stop /p/ which is opposed by a /b/, (which occurs only rarely), its voiced counterpart;

Obstruents	p	b	b^h	
	t	d	d^h	
	ḵ	ĝ	$ĝ^h$	
	k	g	g^h	
	k^w	g^w	g^{wh}	
Fricatives	s			
Nasals	n	m		
Semivowels	i̯	u̯		
Liquids	l	r		
Syllabic liquids and nasals	ḷ	ṛ	ṃ	ṇ
Laryngeals	h_1	h_2	h_3	

Vowels

i			u
	e	o	
		a	
	ē	ō	
		ā	

Figure 1 The IE phonological system.

furthermore, the plain voiceless stops such as /p/ and /t/ are opposed by voiceless palatal stops such as /ḵ/ and /ĝ/. Note that all the vowels except /i/ and /u/ have a short and a long variety: the long varieties /ī/ and /ū/ can be accounted for as sequences of short vowel plus laryngeal; and that the voiceless stops are opposed not only by voiceless palatal stops such as /ḵ/ and /ĝ/, but also by plain voiced stops such as /b/ and /d/.

The resulting phonological system is one which is 'tight' from the comparative point of view, and also from the typological standpoint. That is, the phonological system proposed here is one which occurs within the languages of the world, and contains no segments or oppositions which are unusual in the world's languages.

Morphology

The Noun

In all, eight or nine cases have been proposed for PIE: besides the nominative and accusative, there is the genitive (used primarily for expressing a relationship between two nominals, such as *Bill's hat*); the dative (used mainly to express the notion of *indirect object*, as in Give the book *to Bill*); the ablative (which expresses *separation from*, as in Sara took the book *from Hannah*); the locative (which expresses *stationary location*, as in Maxine is *in the room*); the instrumental (which is used primarily to express *instrumentation* or *means*, as in Charley chopped down the tree *with an axe*); the vocative (used mainly to express *direct address* as in Hey, *Jack*!), and finally, though not unanimously, the directional (mainly used in statements expressing *motion toward*, as in *to the house*). In addition, the protolanguage had three numbers (singular, plural, and dual), as well as three genders (masculine, feminine, and neuter). Adjectives agreed with their head nouns in gender, number, and case, and generally followed the same pattern of inflection as nouns. Pronouns, on the other hand, had their own more or less unique inflectional endings, and were unmarked for gender in the first and second persons. A sample paradigm of a noun in PIE is given in Figure 2. These data represent the following words: Hitt. *ḫūmant-* 'every,' Ved. *pad-*, Gk. *pod-* 'foot,' Av. *kəhrp-* 'body,' *nar* 'man,' and Lat. *vōx* 'voice.' The PIE column records only the inflectional endings (Figure 3).

The Verb

The PIE verb is a complex combination of meaningful elements that indicate certain categories. Specifically, the PIE verb marks *voice*, which indicates the role of the subject; two voices, active and middle, from which the passive developed, are usually postulated; *tense*, which locates the verbal action temporally; the following tenses are usually postulated: present, imperfect, aorist, perfect, and possibly a future; and the *mood*, which indicates the factual content of the utterance from the speaker's point of view. At least the indicative, imperative, and optative are generally reconstructed, and often the subjunctive. The voice, tense, and mood markers are attached to different stems, which indicate aspectual categories, e.g., whether the action is continuous or punctual. The entire verbal complex is indexed to the subject by person and number markers. Finally, verbs can be transitive or intransitive, depending on whether they can take an object (*Mary sees Bill*), or not (*Mary sleeps late*). Although there is no specific marker of transitivity on the IE verb, there are morphemes which can transitivize (like causative *-éye/o-) or detransitivize (like *-eh-) in some roots.

	Hitt.	Ved.	Av.	Gk.	Lat.	PIE
Nom.	*ḫūman-za*	*pā́d (=pā́d -s)*	*kərəf-š*	*poús (=pód-s)*	*vōx (=vōc-s)*	*-s

Figure 3 The present of the verb 'to bear, carry' in reconstructed PIE, with supporting data. Data are arranged according to first, second, and third persons, singular, dual, and plural. From Fortson, IV, Benjamin, W., 2004. Indo-European Language and Culture. Blackwell, Oxford, p. 89.

Adjectives

In PIE, the lexical category of adjective is well documented and is inflected like nouns, usually showing agreement in case, gender, and number: Lat. *bonī cīvēs* (masc.) 'good citizens,' *bonae mulierēs* (fem.) 'good women,' and *bona dōna* (neut.) 'good gifts.' In its oldest stage, PIE did not exhibit any difference between an attributive and a predicative adjective as in *A good friend is a treasure* vs *This man is good*. This distinction is late and occurs only in some branches like Baltic, Slavic and, partly, Germanic. PIE also possessed other adjectival types, such as demonstratives, indefinites, and interrogatives.

Pronouns

PIE possessed a series of personal pronouns that are rather easily reconstructed for the first and second person singular, dual, and plural, whereas for the third person the pronoun was created independently in each branch, mainly from the demonstrative stem.

The relative pronoun was formed basically on two different stems: a stem $*k^{w}o$-/$*k^{w}i$- as in Latin *quī*, *quae*, *quod* or Eng. *who*, *what*; and a stem **jo-* as in Vedic *yas*, *yā́*, *yat*.

Numerals

For PIE, the series of numerals is reconstructed on the base of 10, but there is good evidence that, originally, numeration had a base of 4: the form reconstructed for the number 8 is **(h_3)ókt̄o(w)*, a clear dual form meaning 'twice four.' Moreover in Vedic the word *(h)āsta-*, which derives from **(h_3)ókto-*, means 'hand' probably the so called 'small hand' (four fingers only, excluding the thumb).

It also deserves mention that originally the numbers two and three had different forms for the masculine and the feminine, still preserved in Vedic and Celtic.

Syntax

Even though the syntax of PIE has been intensively investigated during the last five decades, it still remains a field particularly open to new research and is not as well established as is, for instance, morphology. These current limits notwithstanding, there is a small set of features that can be confidently reconstructed for PIE.

PIE as a 'be' Language

The IE protolanguage is generally considered to be a 'be' language rather than a 'have' language, that is, it expresses the possessive relationship such that the *possessum* is the subject in the nominative case, the verb agrees with the subject, and the *possessor* is in the dative case, as in Lat. *mihi est liber* 'the book is at/to me' (I have a book). Similar archaic constructions are found in Slavic, Celtic, Sanskrit, and elsewhere. The alternative, the 'have' language, predicates the possessive relationship with a verb 'to have,' as in Eng. 'John has a book,' found in Germanic, Latvian, Greek, and elsewhere (Baldi and Nuti, 2010).

Subject–Object

PIE was a language in which alignment was of the nominative–accusative type: the subject regularly occurred in the nominative case whereas the object occurred in the accusative, independently of the verb: Lat. *Antoniu-**s*** (Nom.) *libru-**m*** (Acc.) *legit* 'Anthony reads a book.' There are some very old patterns where the 'subject' occurs in the accusative or dative, as in Lat. *mē pudet* 'I regret,' OE *mē likeþ* 'I like,' which probably witness an older stage in which the protolanguage was of the ergative or accusative type. But this is still matter of debate and we leave it aside in this article.

Word Order

In PIE the basic word order, i.e., the order in which the Subject (S), the Verb (V), and the Object (O) occurred in a positive declarative sentence like *John throws the stone*, was SOV. This is not certain beyond any doubt but there is a considerable amount of evidence that points to it: for instance, SOV is the regular word order of the declarative sentence in the oldest languages, such as Hittite GU_4-*ma* AMAR-*ŠU mimmas* 'The cow rejected her calf,' but literally 'cow-but calf-her rejected.

Moreover, it is characteristic of SOV languages that whatever modifies an element usually precedes the element that is modified. This order is well documented, at least in the oldest attested languages, with the genitive before the head noun: Lat. *terrae mōtus* 'earth-quake,' with the adjective preceding the noun: Lat. *rāra avis* 'rare bird'; in the comparisons: Gr. *mélitos glukíōn* 'sweeter than the honey'; and even in the case of the relative clauses: Lat. *cūius regiō, eius religiō* 'whatever one's region, so too his religion.' The order modifier–modified element is clearly documented also by the oldest compounds like Ved. *rājaputrá-* 'son (*putrá-*) of the king (*rāja-*).'

Pronominal Subjects

PIE was a language in which the subject pronouns were not obligatorily expressed, as is the case in many of world's languages but not in Germanic as evidenced by modern English or German. Subject pronouns were employed in contrastive or emphatic contexts only.

Clitics

For PIE, scholars have reconstructed a set of words without their own accents which occurred immediately after the first accented word of the sentence. These words are labeled clitics 'words that lean (on the preceding word).' They are attested in the oldest languages: for instance the conjunction *-kwe, giving Lat. -que as in *senatus populusque* 'The senate and the people' or Gr. *pólemoí te mákhai te* 'and wars and battles,' where the clitic *te* occurs after both nouns.

Subordination

The system of subordinates that is reconstructed for PIE is rather poor: subordination was expressed by means of connecting particles rather than by explicit subordinators. This only means that a true system of subordinate clauses, such as those found in modern languages, had not yet developed in PIE. It is interesting to observe that a huge number of such subordinate clauses were introduced by inflected forms of the relative or the demonstrative stem. Moreover, it should be noted that in PIE there is a small set of verbal nouns (including infinitives and supines) and adjectives (including participles) that is used to express hypotaxis.

Among the different syntactic patterns employed to express subordination with verbal nouns and adjectives, the so-called absolute constructions play a special role. They represent a pattern attested in almost all the IE languages that can be traced back to the protolanguage, despite the fact that the morphological case in which the verbal participle occurs varies from language to language: Lat. *victis hostibus, dux triumphum celebravit* 'after defeating the enemies, the commander celebrated his triumph.' In this example, the participle *victis* occurs in the ablative; but in Greek it occurs in the genitive, in Vedic in the locative, and in Slavic in the dative, just to mention a few examples.

Industrial Cluster Dynamics

Max-Peter Menzel, Institute of Geography, Universität Hamburg, Hamburg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Regional clusters are a pervasive phenomenon. Yet, clusters evolve and exhibit different forms in different places. Clusters are defined by interconnections of geographically concentrated firms in a particular field. This article will describe how these interconnections affect the propensity and shape of clusters. First, it describes the particularity of interconnections between geographically clustered firms and shows how firms substitute permanent colocation by temporarily generated proximity. Second, the article describes how these processes are connected to the emergence and decline of clusters. Third, the article analyzes how socioeconomic contexts affect these interconnections, resulting in variegated clusters.

Introduction

Industries are geographically fragmented and distributed unevenly in space. Geographical agglomerations of interconnected firms and industries are commonly termed as 'clusters.' Clusters like the ICT cluster in Silicon Valley or the Hollywood movie cluster can dominate whole industries. Beside these exceptional examples, clusters are a regular phenomenon of economic activity and important elements in regional economic development.

Porter (2000, p. 15) defines cluster as:

> geographic concentrations of interconnected companies, specialized suppliers, service providers, firms in related industries, and associated institutions (e.g., universities, standards agencies, trade associations) in a particular field that compete but also cooperate.

These interconnections between firms in a particular field define the clusters. The emphasis on interconnections and interdependencies indicate that clusters not only consist of firms in the same industry, but often form along a value chain. The steel and mining cluster in the Ruhr area, for example, also produced machines for steel production and mining (Grabher, 1993). As such, clusters differ from agglomerations of firms of the same industry and are difficult to detect by standard industry classifications. Initiatives to map clusters like www.clustermapping.us for the US or www.clusterobservatory.eu for the EU therefore use bundles of related industries, whereby a regional concentration of different related industries indicates a cluster (cf Porter, 2003).

Another element that distinguishes a cluster from firm agglomerations is its specific institutional environment. Special education infrastructures, industry organizations, and rules of interaction support the activities of firms in the cluster. The specific institutional setting also marks the boundaries of the cluster. Maskell (2001, p. 936) defines the boundaries of the cluster as the "fit between the economic activities carried out by the related companies of the cluster on the one hand and the particular institutional endowment developed over time to assist these activities on the other." These boundaries usually do not necessarily align with administrative boundaries. The geographical extent of clusters might range from a few blocks and streets as found for many media clusters to large areas like in the rural Danish wind turbine cluster. Clusters even pervade country borders like the pharmaceutical cluster around Basel that ranges from Switzerland to Germany and France.

Regional clusters are a pervasive phenomenon. Yet clusters evolve and take different forms in different places. This article will describe the dynamics that affect these processes and in doing so the propensity and shape of clusters. The remainder of the article is structured as follows. The next section will give theoretical explanations for clustering processes. Additionally, it will describe how firms substitute the benefits of permanent colocation by generating temporary forms of geographical proximity. The third section describes the evolution of clusters, i.e., how clusters come into being and how their benefits might turn into disadvantages. The fourth section analyzes how the specific context affects form and extent of spatial clustering, and how changing context conditions over time and space results in variegated clusters. The fifth section concludes and gives an outlook on recent trends in the evolution of regional clusters. The theoretical accounts will be illustrated on the ICT cluster in Silicon Valley as probably the world's most prominent and investigated cluster.

Cluster and Geographical Proximity

Firms in clusters experience stronger growth and faster innovation than those outside clusters (Audretsch and Feldman, 1996; Baptista and Swann, 1998). There are several explanations why geographical proximity between firms might have these effects and the overwhelming ones focus on externalities, i.e., processes taking place outside and between firms (for another explanation see Klepper (2007)). The importance of externalities depends on the possibilities to divide labor. Accordingly, fields like ICT that provide more possibilities of division of labor are stronger clustered than industries like oil refinery (Steinle and Schiele, 2002).

Classical accounts on agglomeration economies already described by Marshall (1920) argue that colocated firms in the same industry benefit from a pooled labor market, knowledge spillovers, and localized supply of nontraded specialized inputs. Contemporary explanations mostly focus on interactions between firms and how interactions in geographical

proximity enhance firm performance. Transaction costs approaches, for example, explain the concentration of firms in geographical space as input–output relations in geographical proximity that reduce transaction costs, either in the form of omitting transport costs (Gordon and Mccann, 2000) or facilitated coordination, especially when firms have to rely on flexible supplier relations to react to volatile markets. Yet, the observations that competition between firms increasingly takes place via innovation than via prices and that innovative activities are increasingly spatially concentrated (Florida, 2005) brought the relation between clusters and innovative activities into focus. This relation is conceptualized by learning via interaction, whereby firms exchange, integrate, and utilize knowledge.

Malmberg and Maskell (2006) elaborate on the particularities of localized learning. First, localized learning describes local capabilities that are "some forms of knowledge creation and exchange that are still very much rooted in the cultural, institutional, and social structures of particular places" (Malmberg and Maskell, 2006, p. 3). In this vein, firms benefit from access to knowledge deeply embedded into a regional context. The more knowledge is codified and globally accessible, the scarcer becomes the embedded knowledge that is hard to codify. The global pharmaceutical industry is a good example of how firms try to get access to these scarce resources. Zeller (2004) describes how the Swiss companies Roche and Novartis established research facilities in the most important clusters of the industry in order to tap into the regional embedded knowledge.

Second, spatial proximity facilitates localized learning on several levels. On the dyadic level, geographical proximity improves learning processes by facilitating face-to-face interaction. Face-to-face interaction allows rapid feedback especially under conditions of vagueness and uncertainty and it enables the transfer of tacit knowledge in form of mimics, gestures, etc. It is "verbal, physical, intentional, and unintentional" (Storper and Venables, 2004, p. 355). This multidimensionality is essential for the transfer of complex knowledge.

Different ways of knowledge exchange, often in the form rumors or recommendations, caused by intended and accidental contacts on various occasions between firm owners and employees within a cluster can create a steady and pervasive stream of information. This stream of information is described with the word 'buzz' (Bathelt et al., 2004; Storper and Venables, 2004). Local buzz allows a firm to monitor other firms, observe what competitors are doing, assess the behavior and results of other firms' activities, and combine their ideas with their own knowledge. Local buzz enables colocated firms to perceive actions of other firms or market developments without deliberately scanning their environment.

Because of the manifold ways of interactions, the particularity of localized learning does not lie in transaction costs or in the efficiency of knowledge transfer. It is rather the diversity of knowledge sources that are perceived and accessible and the type of knowledge that is transferred between actors when they are in the same location (Malmberg and Maskell, 2006). Yet, accessing external knowledge is important for the longevity of a cluster, and efficient knowledge exchanges do not depend on geographical proximity. Mutual understanding between actors and efficient knowledge exchange can also take place within long-term relationships, which often form in geographical proximity, but endure in geographical distance. Firms strategically generate these relations to firms outside the cluster. Trust and efficient knowledge exchange in geographical distance is enabled by a "set of procedural rules involving a sequence of transactions and interactions" (Bathelt et al., 2004, p. 41), which additionally is supported by temporarily generated spatial proximity within projects and meetings (Torre, 2008).

Also 'local buzz' can be substituted. Industry fairs create a temporarily and spatially limited context, where actors from different locations meet, exchange knowledge, give recommendations, and exchange assessments on markets, products, or firms. Fairs thus can be termed as 'temporary clusters' (Maskell et al., 2006), which do not depend on permanent colocation of firms. Accessing knowledge produced elsewhere spills over to other firms in a cluster. In doing so, external relations enhance the quality of local buzz as other firms also get more information about the environment outside the cluster.

How a cluster gives affects the way how firms innovate and produce is exemplary described by Saxenian's (1994) comparison of the computer firms in the Silicon Valley and the Boston area. She described how in the 1990s computer firms in the Silicon Valley by applying firm strategies based on externalities, i.e., low levels of vertical integration and dependence on manifold collaborations with other firms, outperformed Boston computer firms. The strategies of two workstation producers will serve as respective examples (the following is based on Saxenian (1996)).

Apollo was formed in Boston in 1980. Sun was formed in the Silicon Valley 2 years later. Apollo started to establish a proprietary technology. To monopolize its technology and secure its knowledge, Apollo relied to a high degree on in-house research. It developed and produced large parts of the workstation itself, especially the chipsets and operation system. Additionally, it strongly penalized labor mobility. This strategy resulted in a comparatively high degree of vertical integration. Yet, this strategy was also a result of the particular context. As the typical computer producer in Boston was highly vertically integrated, there were few possibilities to vertical disintegrate.

In contrast, Sun adopted a more collaborative and network approach. Its workstation bases on the open UNIX standard to adhere to technologies and components from other firms. Sun only produced prototypes and assembled their workstations. Components were produced by other manufacturers. This network-based model impedes the monopolization of knowledge, but in turn it allowed Sun to easily integrate innovations made by other firms in the Silicon Valley.

The different approaches were also reflected by the founders. The founder of Apollo was 46 years old and its team already had respective experiences from a previous formation. Sun was founded by a team of PhD students in their 20s. Such formations by talented but inexperienced founders were facilitated in an environment like the Silicon Valley where they could rely on external resources. The high propensity to form a firm (and shut it down if not working out) in connection with high rates of labor mobility in the Silicon Valley further contributes to the diffusion of knowledge.

It should be kept in mind that this is a story from the 1990 and more recent studies show that Boston firms also adopted network modes of organization with large reliance on regional

collaboration (Bathelt, 2001). However, these contrasting examples show that the benefits of regional clusters do not simply stem from agglomerations of firms but how firms use and produce externalities, both along and at the same level of a value chain. Geographical proximity is only an enabler of such processes.

Evolution of Clusters

The economic advantages that stem from cluster dynamics are not permanent. In fact, the decline of clusters seems to be caused by factors that were advantages in the past. Grabher (1993) describes the decline of the coal and steel cluster in the Ruhr Area. A conglomerate of unions, firms, and parties tried to sustain the established development path based on mass production despite structural changes in the global industry toward flexible forms of steel production. The Ruhr Area is an example for a region that "became 'locked-in' by the very socioeconomic conditions that once made these regions 'stand out against the rest' [… and …] fell into the trap of 'rigid specialisation'" (Grabher, 1993, p. 256). Other examples are the old Lancashire textile district in the UK and the Detroit automobile cluster. Despite the decline, competitive pressure can lead to high innovation rates. These innovations, however, take place within the existing and exhausted technology path. Long existing, closed, and homogeneous networks were not able to renew the cluster by accessing and integrating new and often external knowledge.

While the decline of clusters is often connected with a too strong inward focus, how clusters emerge, and why they emerge at particular places is a highly disputed topic. Usually, emergence of clusters is connected to the upcoming of new industries. Apart from generic factors like a strong science base, an entrepreneurial culture, and supportive institutions, the requirements of future industries are unknown a priori. No place provides a specific supportive environment for the new industry, which makes it impossible to predict where a new cluster will form (Storper and Walker, 1989). This is reflected by the spatial patterns of firms in new industries. Firms in many regions enter new industries, but clusters develop only in few places (Klepper, 2007). As a result, scholars started to conceptualize cluster emergence not as logical outcome of purposeful actions, but as a stochastic process. "Some seemingly historical accidents" (Krugman, 1991, p. 35) increase the number of new firms at a certain location and once a certain threshold is reached, agglomeration economies will start to work (Arthur, 1994).

Yet, there are some patterns observable regarding cluster emergence. The first is that regional firm entries exhibit some path dependencies. Regions that already provide industries that are related to the new industry exhibit larger amounts of entries. For example, the automobile industry evolved in places with a bicycle and coach industry (Boschma and Wenting, 2007). Firms in related industries are a source of entries, as they can diversify and their employees can spin-off into the new industry. Additionally, related industries provide a possible pool of labor, which allows firms in a new industry to utilize localized resources. Also biotech firms formed in places where 'star scientists'(Zucker and Darby, 1996) were affiliated to the local university and research programs and post-graduate education created a labor pool for the new industry.

A second pattern that is connected to cluster emergence are pervasive intraindustry spin-off processes. From the perspective described above, clusters would emerge at the place where agglomeration effects start first, i.e., the places with most entries. But Romanelli and Feldman (2006) show that this did not take place in the US biotherapeutics industry. Instead, only those regions developed clusters where firms that formed in the early phase spawned spin-offs. Also Klepper (2007) showed the importance of spin-off processes for the emergence of the Detroit automobile cluster. Most spin-offs can be traced to only three firms: Olds, Cadillac, and Buick. Furthermore, while the first wave of entries in a new industry is comparatively spatially dispersed, new industries start to concentrate due to spin-off processes that only occur in some places. Therefore, these spin-off processes that Romanelli and Feldman (2006) term 'second generation growth' are an essential feature for the emergence of clusters.

Apart from emergence and decline, clusters are not bound to a particular field but can change, evolve, and transform. Grabher (1993) illustrates how a new cluster in environmental technologies is emerging in the old coal and steel cluster in the Ruhr Area. The companies of the steel and coal complex acquired the necessary competencies correcting environmental damage that was caused by their industry. Tappi (2005) illustrates how the accordion cluster in Marche/Italy by integrating electronics in their previously traditional musical instruments subsequently moved into electronics. Firms in the cluster got their knowledge on electronics by expatriates from Marche who had lived in the US (Tappi, 2005).

These examples also show that clusters change and move into new fields by integrating new knowledge. Spin-off processes serve to diffuse knowledge that often already is available in the cluster, yet not necessarily accessible. Many structural transformations of clusters are therefore connected with spin-offs that venture in fields deviating from the established path of the cluster.

The evolution of the Silicon Valley is a good example for these dynamics. When the semi-conductor industry emerged in the 50s, the technology was invented in established centers like the Bell Labs in New Jersey. Firms formed at quite different places: Texas Instruments in Dallas, Motorola in Phoenix, DEC in Boston, and Shockley Semiconductor in the area later known as Silicon Valley. These places differ in their locational factors. Places like Boston were equipped well with a scientific infrastructure and industrial base at that time, while for the later Silicon Valley Saxenian (1994) observed that "the only local industry was small-scale food processing and distribution" (Saxenian, 1994, p. 11). As a result, scholars like Arthur (1994) interpret the emergence of the Silicon Valley as an accidental process:

> Certain key persons – the Packards, the Varians, the Shockleys of the industry – happened to set up near Stanford University in the 1940s and 1950s, and the local labor expertize and interfirm markets they helped to create in Santa Clara County made subsequent location there extremely advantageous for the thousands or so that followed them. If these early entrepreneurs had had other predilections, Silicon Valley might well have been somewhere else.
>
> Arthur, 1994, p. 100

Yet, what distinguished the early computer industry in the Silicon Valley were the extensive spin-off processes. Fairchild Semiconductor spun out of Shockley Semiconductor, which again was the parent of several firms like Intel. The milieu these entrepreneurs created made it easy for other entrepreneurs to form a firm.

In the late 1980s, the Silicon Valley also faced a decline. Due to increasing rigidity, large mass-producing chipmakers like Intel and AMD had difficulties to react to a changing market and competition from Japanese semiconductor producers, resulting in 27 000 layoffs in semiconductor and related firms. Yet, this downturn led to a new wave of spin-offs producing small batches of highly specialized chips, which renewed the computer and semiconductor cluster (Saxenian, 1990).

Clusters in Different Socioeconomic Conditions

The previous section described how clusters evolve over time. Yet the processes taking place between firms in clusters are not independent from their socioeconomic environment. The socioeconomic conditions change over time and space and affect the benefits of colocation, the propensities of firms to cluster, and the patterns of cluster evolution.

Clusters in Time

At the beginning of the twentieth century, scholars like Marshall (1920) and Weber (1909) gave first explanation on spatial concentration of firms. Weber (1909) described the economic landscape of his time as one of increasing spatial concentration and agglomeration, which was accelerated by decreasing transportation costs. Marshall (1920) described a shared labor pool, knowledge spillovers, and specialized inputs (Krugman, 1991) as reasons for firms forming 'industrial districts.' These industrial districts were shaped by mostly small- and medium-sized firms. These firms specialized both horizontally, i.e., they produced different products for the same markets, and vertically, i.e., they focused on different functions of the value chain. End producers often sold their products internationally, but gained their supplies from a local supplier base.

Yet, this time already saw the upcoming of the vertical integrated corporation as dominant organizational form. The introduction of organizational inventions like the assembly line and scientific management in connection with increasing standardization of end products allowed dividing production into even smaller steps (Robertson and Langlois, 1995). Due to the constant demand for supply created by the assembly line and in order to internalize productivity gains, manufacturers internalized their backward commodity chains (Sturgeon, 2002). The local form of such a production was the highly vertically integrated factory complex. The paradigmatic example of this developmental model was Ford's River Rouge Plant, developed from 1917 on with up to 100 000 workers, which had coal and iron ore as input and manufactured cars as outputs.

From the 1970s, this production model also came into crisis. Reasons were an increasingly heterogeneous and volatile demand which could not be met by Fordist mass production; an exhaustion of productivity gains by deeper technical division of labor; and increased competition from firms that applied more flexible production models, like Japanese car producers.

In the 1980s, Italian economists recognized that particular regions in Northeastern and Central Italy unexpectedly exhibited a positive economic performance. Those regions like the Emilia Romagna were shaped by geographic concentrations of vertically disintegrated small and medium firms that focused on highly specific fields like sofa or shoe manufacturing and performed a craft-based and neo-artisanal production (Becattini, 2002). Upon these examples, Marshall's ides of Industrial district were rediscovered. Yet, compared to Marshall's industrial districts where coordination took place via markets, the Italian examples exhibited manifold nonmarked-based interconnections between firms (Piore and Sabel, 1984). Scholars described economic relations embodied in personal relations, embeddedness of actors in regional networks that penalized opportunistic behavior, and regional institutions that guided interactions as distinct factor of the Italian industrial districts (Becattini, 2002).

This setting enabled trust-based relationships between firms that were necessary to adjust products, supplies, and respective relations to volatile and fragmented markets. Similar forms of localized production and innovation systems around a value chain that performed above average were also found in other places like Baden-Württemberg/Germany or the Silicon Valley. Scholars like Piore and Sabel (1984) saw the flexibility of network-based interfirm relations as a paradigm for a new and post-Fordist form of production. In doing, the foundation for the contemporary concept of the regional cluster was laid.

Clusters in Varieties of Capitalism

The previous section described how the activities of firms and their propensity to cluster changed with changing socioeconomic conditions. These conditions differ not only in time, but also in space. Institutional approaches like the Varieties of Capitalism approach (Hall and Soskice, 2001) argue that firms choose forms of coordination that are institutionally supported. Institutional differences between countries would lead to different behaviors of firms and accordingly to different forms of clusters.

The Varieties of Capitalism approach distinguishes between two archetypes of capitalism: liberal (LME) and coordinated (CME) market economies. In LMEs like the US, coordination between economic actors mainly takes place via markets, competitive relations, contracting, and internal corporate hierarchies. Arm-length relations between firms allow firms to quickly adjusting and switching processes and resources toward new activities. This quality benefits the firms in LMEs in the exploitation of technological developments independent of established fields and outside of existing paths or paradigms.

In CMEs like Germany, nonmarket institutions support strategic interactions and collaborations to address and align the needs of different stakeholders. In such an entangled environment, firms benefit from investing in assets "whose returns depend heavily on the active cooperation of others" (Hall and Soskice, 2001, p. 17). As a result, firms benefit from incrementally and cumulatively building up resources within or in connection to established fields.

This difference in connection to established resources and establishing distinct resources also affects cluster evolution. While the Silicon Valley as example for a cluster in LMEs quickly built up its distinct resources, clusters in LMEs evolve with stronger connection to established fields (Storper, 2009). When the Silicon Valley emerged in the US, the paradigmatic clusters that formed in Europe were the industrial districts in Italy or Baden-Württemberg/Germany, which yet used new technologies but formed around traditional industries like machine or furniture production.

In Asia, cluster evolution again follows a different pattern. The particularities of Asian economies can hardly be grasped by the categories developed within the Varieties of Capitalism approach. Furthermore, the varieties among Asian economies are even larger than among Western economies (Witt and Redding, 2013). China, for example, presented a state-led capitalism with direct interventions and indirect interventions by its state-owned companies, mediated by informal networks, with again different regional varieties (Zhang and Peck, 2014). This institutional variety results in variegated forms of cluster evolution, whose different forms cannot be described in this article. But an example for cluster evolution in the Chinese province Guangdong is described in Rubini et al. (2015).

Conclusion

The intention of this article was to describe the dynamics of regional industrial clusters. Clusters are not only a geographically concentrated group of firms, but rather defined by their interconnections. The quality and characteristics of these interconnections affect the performance of clustered firms. Clusters also change via these interconnections.

The paper started with the particularity of interconnections between spatially clustered firms and conceptualized them as localized learning (Malmberg and Maskell, 2006). Additionally, it showed that firms can substitute permanent physical proximity by organizing temporarily generated proximity like 'temporary clusters' (Maskell et al., 2006) in the form of industry fairs and projects. Learning within and outside the cluster are mutually enhancing, as knowledge relations outside the cluster improve knowledge flows within the cluster. In this vein, access to external knowledge is mandatory for the longevity of regional clusters. When firms rely too much on knowledge flows within the cluster, the tightly regionally embedded firms fail to perceive developments outside the cluster. As a result, the benefits of knowledge exchange in spatial proximity turn into disadvantages and the cluster might decline.

Institutions guide forms of localized learning. In different institutional environments and under different socioeconomic conditions, localized learning exhibits different qualities and characteristics. Clusters from the time of Marshall differ from those of today and nowadays clusters vary between countries and regions. Even in the same industry, clusters are time and place specific.

The intention of the article was to shed some light onto the dynamics that affect cluster evolution. But the rationales under which clusters evolve in space constantly change. Contemporary literature mainly focuses on clusters as entity to improve the innovativeness of firms. Yet, some clusters seem to evolve in a different way and might give examples for the evolution of other clusters.

The Silicon Valley is surely an adequate starting point for such an analysis. Sturgeon (2003) described in the Silicon Valley ICT industry an increasing trend toward modularization of supplier relations. Modularity describes a product architecture where the components of a product are interchangeable without adjustments in other components. Particular components can be integrated in different versions and generations of a product. A modular product architecture also affects supplier relations. Standardization of component interfaces and codification of product specifications disembed relations between manufacturers and suppliers from their social and special context. Suppliers become interchangeable (Baldwin and Clark, 1997) and Silicon Valley manufacturers increasingly outsourced their production to contract manufacturers on other regions and countries, especially China and Taiwan. Yet, to mediate the volatility of modular organized interactions, key suppliers moved their (regional) headquarters to the Silicon Valley. In doing so, the ICT cluster changed its developmental rationale from innovation of new products to local organization of global value chains (Sturgeon, 2003).

Modularization of production affects interconnections between firms within and outside clusters. Resembling processes can be detected in many industries from automobiles to aircraft production. A deeper implementation and broader diffusion of modular production in different industries will therefore affect the general dynamics behind cluster evolution and in doing so the general fragmentation of economic activity in space.

Industrial Dynamics: Patenting Perspectives

Mei-Chih Hu, National Tsing Hua University, Hsinchu, Taiwan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article is based on the premise that the dynamics of an industry are not only driven by patenting activities at the levels of country, industry, and firm, but have also coevolved along with the various developmental stages of the industrial cycles in each country. Consequently, most merger and acquisition activity, manpower recruitment, patent licensing and lawsuits, and antitrust prosecutions take place in the Trilateral Patent Offices of the United States, Japan, and Europe. The most prolific and fastest-growing patentees (in the United States, Japan, Germany, Korea, Taiwan, and China) are those that are closely linked with information and communication technologies and the biotechnology industries. Emerging policy challenges and future research directions are also elaborated in order to better describe the role of patenting in the evolving industrial dynamics of the twenty-first century.

Introduction

The study of industrial dynamics goes beyond the traditional disciplines of industrial organization studies to encompass a wide range of characteristics of firms within a country or an industry, in terms of size, entry and exit, innovation performance, research and development (R&D) expenditure, and innovation strategies, and it deals with comparisons of one period or geographic region with another (Malerba and Orsenigo, 1996). Industrial dynamics is considered to be among the most interesting and rewarding fields of research, since its nature is knowledge- and strategy-centric, and it is constituted by a number of networks and driven by various types of industrial actors (including new entrants, incumbents, governments, academy, business associations, and regulatory agencies). The ultimate goal is promoting the growth of industrial companies and building stronger competitiveness for them, through the creation and diffusion of knowledge within and across the industry.

Given that knowledge diffusion is critical for building innovation capability in a dynamic industry, the development of knowledge sources, delivery processes, and interactions as dynamic elements has become essential, as has the contribution of technological and institutional actors. Knowledge creation and diffusion is effected through a range of channels, including foreign direct investment (FDI), joint ventures, international trade, technological licensing, imports of capital goods, cooperative research projects, researcher networks, movement of personnel, and the scientific literature. In this complex situation, codified knowledge such as patents can play a role as legal documents, since they contain reliable and traceable records of knowledge creation and diffusion. This makes patenting activity one of the best and most accessible proxies for exploring the evolution of industrial dynamics, especially in knowledge-intensive high-tech industries. This article, based on patent perspectives, is intended to summarize the state of current knowledge on industrial dynamics and to discuss the major challenges presented by current intellectual property systems, through which emerging policy implications and future research directions may be developed.

Worldwide International Patenting Activity

A patent is a temporary monopoly awarded for the commercial exploitation of a newly invented device. The grant of a patent implies that such a device would not appear obvious to a skilled practitioner of the relevant technology. While researchers usually use industrial production, value chain networks, and market share to evaluate an industry, the volume of patenting applied for and approved can be a further important indicator of industrial dynamics.

According to the cooperative Trilateral Patent Office, most patent applications are to the USPTO, the JPO, and the EPO, while worldwide patent demand rose from 2 586 045 in 2000 to 6 082 067 in 2009, which is more than a twofold increase in a decade, corresponding to an average annual increase of about 13%. Within this overall total, there has, however, been a marked difference in patenting propensity between the advanced countries and latecomer countries. First filings accomplished in the advanced countries over the period 2003–09 registered a rise of just 2.6% (USPTO) and 0.97% (EPO) and a fall of 3.8% (JPO). In comparison, patenting activity in the emerging latecomer countries, such as that to China's SIPO, Taiwanese IPO, and Indian IPO exhibit an approximately 20% increasing rate of first filings over the same decade, indicating the rapid diffusion and internationalization of patent knowledge spillovers in these emerging countries.

The patent document is considered to be one of the major indicators of cutting-edge technology, embedding as it does great commercial value (World Intellectual Property Organization (WIPO), 1999). WIPO reported that over 90% of R&D achievements were disclosed in the patent gazettes, while 80% of them were not revealed in academic journals or the technical literature. Moreover, the world's No. 1 patentee, IBM, earns over US$1 billion in royalties per year. Patents and patenting information represent some of a company's most valuable assets and decisive factors in company strategy, protecting R&D achievements, raising research performance, creating profits and new business models, and maintaining competitive advantage in the market.

Patent Statistics as Indicators of Innovation and Industrial Dynamics

While technological innovation cannot be precisely measured, patenting rates have long been considered a well-grounded proxy for level of innovation. Though the sources of patents may introduce bias, the advantages associated with using international patents are described in many prior studies (e.g., Soete, 1987). In addition, a strong link between foreign patent grants and domestic R&D investments, as well as between foreign patents and FDIs demonstrates that patenting activity is an important factor in international trade. While some researchers have emphasized that involvement in global production networks is an important source of knowledge for advancing export performance in late industrializing countries, other studies have explored the importance of the different relationship between technology and international business trade performance (e.g., Dosi et al., 1990). To various degrees, all the literature supports the positive relationships between knowledge, innovation activity, and economic or industry performance in both advanced and latecomer countries.

On the country and industry levels, researchers associated with the National Bureau of Economic Research have developed methodologies for studying the flow of knowledge from one country or industry to another, using patent statistics. In particular, data from patents taken out in the USPTO by both American and foreign firms have enabled researchers to trace the influence of knowledge spillovers and degrees of specialization associated with industrial clustering (Jaffe and Trajtenberg, 1999). Studies have used this USPTO patenting activity to examine the experiences of specific institutions, such as biological resource centers (Furman and Stern, 2004), individual industries, such as solar photovoltaic (Wu and Mathews, 2012), and international knowledge flow, such as that between Taiwan and South Korea (Hu and Jaffe, 2003). Many have argued that only certain types of innovation can be measured, and that many important innovations are not patented, for instance in food and tobacco; some patents are awarded for very modest discoveries (e.g., in basic metals and automotive techniques). Nevertheless, patent activities are still widely recognized as an appropriate indicator in the context of high-tech industries.

On the level of the firm, patent data are a valuable information source allowing decision makers to assess their own technology portfolio in comparison with their competitors within and across the industry, including the ability to assess the attractiveness of technologies, especially those posing a threat, or new opportunities for the existing business; to recognize strategic changes in the firm's competitive environment; to identify and assess external sources for knowledge generation (e.g., merger and acquisitions (M&A) and R&D alliances); to assess the status of patent appropriation in new business areas; to evaluate important market partners, especially customers and suppliers to determine whether the firm's R&D strategy is in alignment with that of its major customers and competent suppliers; and to improve human resource management pertaining to leading inventors in specific technological fields. In summary, integrated patent information can act as a quick and efficient monitoring system for capturing the industrial dynamics through timely review and update of competitive portfolio analysis, technology trends, market segmentations, and business opportunities within and across industries, as shown in Figure 1.

Worldwide Industrial Dynamics: Patenting Perspectives

The US industrial market is widely recognized as the largest and the most technologically advanced in the world and the US patent statistics are reliable indicators because of the general screening procedures imposed by the USPTO. With all their deficiencies, then, patenting rates, and particularly data on what the USPTO calls 'utility patents' (which represent real inventiveness, rather than minor improvements or other 'noise' in the overall data), represent a uniform and time-robust measure of innovative output with an immediate economic significance, since the time and trouble involved in seeking patents in the USPTO system has the effect of filtering out trivial or idiosyncratic innovations. Accordingly, worldwide industrial dynamics will be explored in terms of patenting activity at the levels of country, industry, and firm, as follows.

Country-Level Patenting Comparisons

Many studies examine the extent of innovation by using patent data for advanced countries (mainly in the Organization for

Economic Cooperation and Development (OECD)) while tending to ignore the rapidly increasing patenting activity in emerging latecomer countries. A few studies have indicated that the overall patenting activity of the newly industrializing countries had been quite low in early times, but has gone up substantially in the past decade, and that the growth in patenting has reflected a rise in technological capability over time in these countries. The recent trend is more dramatic, as shown in Table 1, which shows that the advanced countries (particularly the United States, Japan, and Germany) enjoyed the highest accumulation of innovation capacity throughout the period of 1963–2010, while Taiwan and Korea are listed, respectively, as the USPTO's fourth and fifth most active patentees in the 2000s. Figure 2 further indicates that Taiwan and Korea, with their highest compound average growth rate in the 2000s, aggressively built their innovation capabilities since the 1990s, while fast-growing China and India are positioned at a lower base, but secured the highest annual growth rate starting in the 2000s. This massive increase in innovative capabilities, in terms of patenting activity, in these latecomer countries reflected the effect of international knowledge spillovers in the direction of the newly industrialized economies and their achievements on the frontier of technological progress in certain areas (Wu and Mathews, 2012). The three advanced countries (the United States, Japan, and Germany) and the three latecomer countries (Korea, Taiwan, and China)

Figure 2 Patenting activity and compound average growth rate: G7 vs East Asian 5 vs reference countries, 1981–2010 by 10 years. Source: USPTO and compiled by this study.

Figure 3 Comparisons of patent per capita in the USPTO, 1981–2010 by 10 years. Source: USPTO and World Bank and calculated by the author.

were the most prolific or fast-growing patentees in the USPTO in the 2000s. (Even though India presents a high annual growth rate during the last three decades (Table 1), this article does not include India in further discussions of its biotechnology specialization area due to its low absolute number of patents. However, see a 2007 special issue for Indian pharmaceutical industry at *Technology Analysis & Strategic Management*, volume 19, issue 5, for the effect of Indian patenting activity on the development of its biotechnology industry.) It is thus worthwhile examining how the patenting activities with respect to these six countries have influenced the global industrial dynamics in their specialized areas.

Since the 1990s, the top five patentees in the USPTO, in terms of patents per capita, have been the United States, Japan, Taiwan, Germany, and Korea, as shown in Figure 3. With country size acting as one of the growth-driven impetuses, China secured the position as the fastest growing patentee in the 2000s, but the rate of patent per capita is overshadowed by its huge population (1.3 billion), implying an even greater opportunity for potential growth and innovation capacity.

Industry-Level Patenting Comparisons

Table 2 demonstrates that the top patenting activities in the Trilateral Offices (USPTO, EPO, and JPO) essentially converge and are concentrated in the high-tech and knowledge-intensive industries, namely medical and biotechnology (A61), semiconductors (H01), communications (H04), and opto-electronics (G01 and G06), while renewable energies are also starting to attract interest. It can also be noted that the patenting activity of EPO is also prolific in the automobile industry (B60, mostly smart cars) since the second half of the 2000s. Indeed, these high-tech and knowledge-intensive industries have been found increasingly important in focusing on intellectual property appropriation (particularly of patents), which then in turn lead to a rapidly changing and transforming dynamic industry. This will be discussed in relation to the situation in the global light-emitting diode (LED) industry.

The above argument is further reflected in country-level patenting activity, as shown in the six prolific patentees in the USPTO (the United States, Japan, Germany, Taiwan, Korea, and China) in Table 3. In terms of international patent classifications (IPCs), the technology specialization is reflected perfectly in the foci of economic growth in each prolific patenting country (the IPC is an international standard for classifying technologies in patent applications; it divides technologies into eight sections with approximately 70 000 subdivisions (see WIPO for details, www.wipo.int/classifications/ipc/en/general/preface.html). The details of IPCs description and search can be accessed at http://v3.espacenet.com/eclasrch?classification=ecla&locale=en_V3). The US patenting activity was most productive in the biotechnology area (IPC: A61K) in the 1990s and switched to a fundamental physics area for multicomputer digital processing (G06F) in the 2000s, while other countries retained their primary focus across the 1990s and 2000s: Japan paid particular attention to semiconductor devices (H01L); Germany takes biopharmaceuticals, especially organic compounds (C07D), as the priority; Taiwan and Korea as latecomers followed Japan in a 'flying geese' model in developing semiconductors (H01L) as national campaigns; and China has focused on general and operational chemical and physical processes (B01J) appropriate to its lower level of economic development.

It is interesting to note that the patenting rates in the semiconductor and information technology sectors in Japan, Taiwan, and Korea effectively retain the flying geese model, in which knowledge spillovers and technology progress is led by Japan and transferred to Taiwan and Korea, the Asian latecomer countries. Indeed, the importance of knowledge diffusion is particularly recognized in these East Asian latecomer countries, by way of their evolving development of strategic high-tech industries, starting with personal computers in the 1980s and progressing to semiconductors in the 1990s, optoelectronics (particularly liquid crystal displays (LCDs)) in the 2000s, and recently, starting in mid-2005, moving onto LED and solar photovoltaic cells (Mathews et al., 2011). Meanwhile, the flying geese model for patenting activity has been the transfer mechanism for China only since the 2000s, when semiconductor (H01L) and information technologies (H05K and G06F) emerged significantly, despite that the industrial innovation priority in that country is focused on general physical and chemical processing equipment (B01J) due to its lower capability for innovation and its restricted economic base. The patenting datasets cited here not only reflect the

evolving industrial competitive advantage in each country but also illustrate the national strategies toward industrial development (Hu and Mathews, 2005, 2008).

Firm-Level Patenting Comparisons

The top patentees listed in the Trilateral Cooperation Office present an even clearer picture to further verify the dominance of information and communication technologies (ICTs) in the global market. The top 10 organizations listed in both USPTO and JPO over the first decade of the 2000s are overwhelmingly dominated by international electronics and communication companies. In comparison, the EPO is also led by the European ICT giants Siemens (No. 1) and Phillips (No. 2) with two exceptions, BASF and Bayer (both German Corporations) from chemical and medical industries, which are listed as No. 3 and No. 10, respectively in 2010. In the USPTO as shown in Table 4, IBM has been the No. 1 patentee for more than 20 years and Samsung become the No. 2 prolific patentee for the first time in 2006 while Microsoft jumped into the top 10 list. Indeed, the patenting rates for both IBM and Samsung are seen to have doubled in a decade, so as to secure the No. 1 and No. 2 positions, respectively. It is interesting to note that, of the Top 10, four are US firms, four are Japanese *keiretsus*, and two are Korean *chaebols*, while no European firm has penetrated to the top echelons throughout the investigation period until 2010.

The significance of patenting activities for securing technology and business model appropriation in the global market has induced both international leaders and technology latecomers to put a great deal of effort into pursuing stronger patent portfolios. While the risks and costs of developing cutting-edge products are rapidly increasing, the efforts of securing intellectual property appropriation are closely tied to

the involved multifaceted character of the innovation that has boomed since the 2000s. Consequently, patenting licensing activities, multifarious patent trolls, and frequent patent litigations have come to be a critical part of the business strategies in the creation of legal and value-creating assets. These resultant business activities not only challenge the usage of patent (intellectual property) for innovation and knowledge creation but also drive the evolution of industrial dynamics (Reichman, 2009; Fink and Maskus, 2005). These challenges derived from industrial dynamics are discussed in the context of global LED industrial development, with the intent that future emerging directions in theory and research can be illuminated.

Case: Evolution of the Global LED Industry Driven by Technological Appropriability (Patents)

The first commercialized low-brightness LED was developed by the US firm General Electric (GE) as early as 1962, but the LED lighting era did not kick off until the US Hewlett–Packard and Japanese Toshiba successfully codeveloped the first high brightness LED in 1991. During the 1990s, the appropriation of LED technology was dominated by first movers in the United States (GE, RCA, and Cree) and Europe (Osram and Phillips). However, the technological appropriation was shifted and shaped by the innovative Japanese latecomer Nichia in the mid-1990s, when it achieved a technological breakthrough for the high-brightness indium gallium nitride blue LED (InGaN, a III–V compound semiconductor material). This technological breakthrough immediately led the industry to move into the introductory stage, while the world's first white LED came onto the market in 1996. This technological breakthrough enabled Nichia to monopolize the global LED market through its strong patent portfolios while winning every patent lawsuit up until 2002. However, the patent portfolio built by Nichia was, to a certain degree, still based on the previous accumulated knowledge created by US and European first movers. In 2002, Nichia's patent lawsuit failed for the first time to prevent infringement by the other four leaders Cree, Phillips Lumileds, Toyota Gosei, and Osram. Thereafter, the five leaders reached cross-licensing agreements with one another in order to build a strong entry barrier against technological latecomers and led the industry move into the earlier growth stage.

The global LED industry remains restricted by the appropriability of technology (through patents) leading to market competition in an oligopoly. To push the industry into the rapid growth stage, a round-table discussion on the LED manufacturing roadmap convened by the US Department of Energy reported in July 2010 (Department of Energy, 2010); the round-table experts, after several discussions, identified seven priority tasks for LED manufacturing, some associated with luminaire manufacturing and others to do with LED chips and packages. These tasks have the immediate goals of increasing emitting efficiency through technological improvement in the manufacturing process (e.g., mechanical/thermal, packaging, and drivers), through the setting of industrial standards in order to drive down the current LED manufacturing costs by 80–90%, by the 2020s (Department of Energy, 2010: p. 6). For those firms at the technological frontier (Cree, Nichia, TG, Phillips, and Osram), these manufacturing capabilities depend neither on their expertise nor on their embedded resources; nevertheless, they are necessary to closely connect the technological fast-followers (the Korean, Taiwanese, and Chinese players who specialize in mass production) with the first movers via technological appropriability. This evolution thus exhibits a double-edged challenge for the LED technological fast followers. On one hand, the latecomer disadvantage is constrained by the intellectual property rights (mainly patents) possessed by technological first movers, such as patented phosphor materials and high-end equipment. On the other hand, this constraint, in its turn, provides an opportunity for technological fast followers to build the subsequent capabilities complementary with those at the technological frontiers (mainly patents and expertise) in the industrial growth stage (Hu, 2012).

Consequently, the global market share of the top five international leaders in LED (Nichia, Osram, Cree, Phillips Lumiled, and Toyota Gosei) has been reduced from 80% in 2004 to 39% in 2009, while that of the top five latecomers (Korean Samsung LED and Seoul Semi, and Taiwanese Epistar, Everlight, and Optotech) increased from 17% in 2007 to 30% in 2010. The increased market share of the technology latecomers is derived through links with the technological appropriability of the five international leaders, and by extending them through OEM licensing, patent licensing, joint ventures, and manpower recruitment, as shown in Figure 4.

It is clear that the current technological regime is dominated by technological leaders in the advanced countries, illustrated by the patenting activities of the USPTO, EPO, and JPO. However, this industrial dynamic is continuously evolving, while a different latecomer strategy (from Korea and Taiwan) has been evident in the development of the LED industry in China. The shortcomings of technological appropriation (through intellectual property), as reflected in Table 2 and Figure 3, have seriously damaged the status of Chinese LED players in the global market. Even so, China's LED industry has been burgeoning, due to government subsidies and the official inauguration of the 12th Five Year Plan for National Economic and Social Development from 2011 to 2015. Taking advantage of the huge domestic market, China's solid government support of a large number of public projects has provided the opportunity for growth for numerous small Chinese LED firms and, since it is focused on the domestic market (without intellectual property issues), defers the effect of intellectual property on technology acquisition, transfer, diffusion, and internalization, while it helps the endogenous Chinese firms to build and accumulate their innovation capabilities and patent portfolios based on setting new domestic industrial standards, product specifications, and application systems. This effect has been demonstrated by the rapid growth of China's patenting activity in the Trilateral patent offices (and particularly in the USPTO, as shown in Table 1 and Figure 2). The goal of China's strategy has been to shift the focal of industrial dynamics away from the existing technological regime built by the international leaders and to mitigate the latecomer disadvantage by creating a new technological regime.

The development of the global LED industry has clearly vindicated the patenting practices explored in the previous sections, where intellectual property appropriation (particularly of patents) has not only led to a rapidly changing and transforming dynamic industry, but has also coevolved with it.

Concluding Remarks

The ultimate goal of intellectual property protection is to facilitate economic growth derived from innovations, so as to increase social welfare as a whole. However, due to the differing stages of industrial development in each country, the aggressive series of patenting races in the so-called high-tech industries have challenged the existing system for both the advanced and latecomer countries, as demonstrated in the case of the global LED industry described above. In advanced countries such as the United States, the cumulative cost of patent litigations has compromised the benefit of patented innovations, particularly for upstream research. Reichman (2009) has thus suggested wider use and transparency of publicly funded research results and nonexclusive licensing, in the spirit of antiblocking or public interest, in which the legal schemes for manpower mobility, such as *Non-Compete Covenants*, *Inter-Institutional Agreement*, and the *Material Transfer Agreement* require careful specification. In latecomer countries such as China and India, the intellectual property regime is designed to stimulate industrial development through rapid knowledge diffusion and by building indigenous innovation capability (Kim et al., 2012). For example, compulsory licensing is enforced for those inventors who are unable or unwilling to practice their inventions in China, while minor adaptive invention is outlawed in India in order to ensure the novelty of innovation which successfully upgraded its bio-pharmaceutical industry onto the global market since the 2000s. The link between patents and trade policy was made explicit by the international TRIPS framework, adopted and enforced as part of the creation of the WTO in 2001.

These examples demonstrate that the various development stages of industrial dynamics evolve with the industrial cycle while the patenting and industrial activities between technological leaders and latecomers are closely linked, as shown in Figure 5. During the embryonic and introductory stages, IP wars emerge among various types of technology breakthrough and competition before specific industrial standards can be established by technological leaders to steer the industry through its initial growth stages. Based on the guidelines, dominating industrial standards, building stronger IP portfolios in the patent race, IP licensing, M&A activity, and manpower recruitment have become the main strategies of technological leaders during the industrial growth stage, while this competition has extended the existing technological regime and has transformed it from a cost basis to a quality basis, with an abundance of differentiated products systematically developed by the technological latecomers. The surviving companies then form an oligopolistic industry in the latter growth stage, while IP lawsuits, antitrust, and fair-trade issues become critical elements in driving the next generation of technology and developing system services and platform strategies in the mature stage. At this stage, the latecomers (with limited technological appropriability) must then either focus on new technology generation and applications (as in Korea and Taiwan) or try to shift the focal of

Figure 5 Industrial dynamics evolved over the industrial cycle and intellectual property system.

industrial dynamics away from the existing technological regime (as in China) in order to compete with the incumbents and international leaders. Driven by the appropriability of intellectual property rights (and especially patents), these coevolving and cyclical industrial dynamics have been evidenced in many studies (for example, Hu (2012)) and are especially apparent in the knowledge-intensive ICT and biotechnological industries as found in the Trilateral patent offices.

Even though the role of intellectual property is considered and strategized differently for technological leaders and latecomers in the context of industrial- and firm-level dynamics, the changing modes of innovation across the high-tech industrial dynamics suggest that policy makers at country-level should pay attention not only to the traditional approach of merely building physical knowledge infrastructure (e.g., hardware Internet accessibility and competition regulation) but should also explore socially accessible knowledge mechanisms (e.g., fluid manpower flows, open data for publicly funded research, and networks, as shown in the LED case) along the journey from innovation to the market. Based on the WTO framework, this may include the secondary design of an adaptive intellectual property legal system so as to meet the indigenous needs of different stages of industrial development over time, as well as establishing and facilitating transparent markets for technology and open collaboration. Along with this, future research may need to further explore the extent and magnitude of patent licensing, patent litigation, and fair-trade issues over the various development stages of the industrial cycle, particularly for their different impact toward technological leaders and latecomers, as demonstrated in last section.

Industrial Ecology

Reid Lifset and Thomas E Graedel, School of Forestry & Environmental Studies, New Haven, CT, USA

Published by Elsevier Ltd.

Abstract

Industrial ecology is a rapidly growing field that examines the flow of materials and energy at various scales as part of the study and pursuit of sustainable production and consumption. Originating in part from an analogy to resource flows in ecosystems with an emphasis on the environmental gains from cyclical use of resources, the field emphasizes the importance of a systems perspective in environmental analysis, management, and policy. It includes tools such as life cycle assessment (LCA), material flow analysis (MFA), input-output analysis, and design for environment (DfE). Concepts such as industrial symbiosis, eco-efficiency, dematerialization, urban metabolism are central to the field.

Setting out the goals and boundaries of an emerging field is a hapless task. Set them too conservatively and the potential of the field is thwarted. Set them too expansively and the field loses its distinctive identity. Spend too much time on this task and scarce resources may be diverted from making concrete progress in the field.

But in a field with a name as provocative and oxymoronic as industrial ecology, the description of the goals and definitions is crucial. Hence this introductory chapter describes the field of industrial ecology, identifying its key topics, characteristic approaches, and tools. The objective is to provide a map of the endeavors that comprise industrial ecology and how those endeavors relate to each other. In doing so, we seek to provide a common basis of discussion, allowing us then to delve into more conceptual discussions of the nature of the field.

No field has unanimity on goals and boundaries. A field as new and as ambitious as industrial ecology surely has a long way to go to achieve even a measure of consensus on these matters, but, as we hope this article shows, there is much that is coalescing in research, analysis, and practice.

Defining Industrial Ecology

The very name *industrial ecology* conveys some of the content of the field. Industrial ecology is *industrial* in that it focuses on product design and manufacturing processes. It views firms as agents for environmental improvement because they possess the technological expertise that is critical to the successful execution of environmentally informed design of products and processes. Industry, as the portion of society that produces most goods and services, is a focus because it is an important but not exclusive source of environmental damage.

Industrial ecology is *ecological* in at least two senses. As argued in the seminal publication by Frosch and Gallopoulos (1989) that did much to coalesce this field, industrial ecology looks to nonhuman 'natural' ecosystems as models for industrial activity.[1] This is what some researchers have dubbed the 'biological analogy' (Wernick and Ausubel, 1997; Allenby and Cooper, 1994). Many biological ecosystems are especially effective at recycling resources and thus are held out as exemplars for efficient cycling of materials and energy in industry. The most conspicuous example of industrial reuse and recycling is an increasingly famous industrial district in Kalundborg, Denmark (Ehrenfeld and Gertler, 1997: Chapter 27). The district contains a cluster of industrial facilities including an oil refinery, a power plant, a pharmaceutical fermentation plant, and a wallboard factory. These facilities exchange byproducts and what would otherwise be called wastes. The network of exchanges has been dubbed 'industrial symbiosis' as an explicit analogy to the mutually beneficial relationships found in nature and labeled as symbiotic by biologists.

Second, industrial ecology places human technological activity – industry in the widest sense – in the context of the larger ecosystems that support it, examining the sources of resources used in society and the sinks that may act to absorb or detoxify wastes. This latter sense of 'ecological' links industrial ecology to questions of carrying capacity and ecological resilience, asking whether, how, and to what degree technological society is perturbing or undermining the ecosystems that provide critical services to humanity. Put more simply, economic systems are viewed, not in isolation from their surrounding systems, but in concert with them.

Robert White, the former president of the US National Academy of Engineering, summarized these elements by defining industrial ecology as … "the study of the flows of materials and energy in industrial and consumer activities, of the effects of these flows on the environment, and of the influences of economic, political, regulatory, and social factors on the flow, use, and transformation of resources" (White, 1994).

This broad description of the content of industrial ecology can be made more concrete by examining the core elements or foci in the field:

- the biological analogy,
- the use of systems perspectives,
- the role of technological change,
- the role of companies,
- dematerialization and eco-efficiency, and
- forward-looking research and practice.

The Biological Analogy

The biological analogy has been applied principally at the level of facilities, districts, and regions, using notions borrowed from ecosystem ecology regarding the flow and especially the cycling

of materials, nutrients, and energy in ecosystems as a potential model for relationships between facilities and firms. The archetypal example is the industrial symbiosis in Kalundborg, but the search for other such arrangements and even more conspicuously the effort to establish such symbiotic networks is emblematic of industrial ecology – so much so that many with only passing familiarity of the field have mistakenly thought that industrial ecology focused only on efforts to establish eco-industrial parks.

This analogy has been posited more generically as well, not merely with respect to geographically adjacent facilities. Graedel and Allenby (1995) have offered a typology of ecosystems varying according to the degree to which they rely on external inputs (energy and materials) and on release of wastes to an external environment. Expressed another way, the ecosystems vary according to the linearity of their resource flows as shown in **Figure 1**: type I is the most linear and reliant on external resources and sinks; type III stands at the other extreme, having the greatest degree of cycling and least reliance on external resources and sinks. The efficient cycling of resources in a biological system is held out as an ideal for industrial systems at many scales. This framework thus connects the biological analogy to strong emphasis in industrial ecology on the importance of closing material cycles or 'loop closing.'

The biological analogy has been explored in other ways. The ecological analogy has, for example, been applied to products as a source of design inspiration (Benyus, 1997), as a framework for characterizing product relationships (Levine, 1999), and as a model for organizational interactions in technological 'food webs' at the sector or regional levels (Hardy and Graedel, 2002; Frosch et al., 1997).

The analogy to ecology is suggestive in other respects (Ehrenfeld, 1997). It points to the concepts of community and diversity and its contribution to system resilience and stability as fundamental properties of ecosystems – and as possible models of a different sort for industrial activity. These dimensions of the analogy may point to ways to integrate organizational aspects of environmental management more deeply into the core of industrial ecology, but they have not been as extensively explored as the use of ecosystem ecology with its emphasis on flows and cycling of resources. As Andrews (2000) points out, there are long-standing bodies of scholarship that apply the ecological notions directly to social, as opposed to technological, dimensions of human activity including organizational, human, and political ecology. The biological analogy is not confined to ecological similes. A more quantitative embodiment of the biological analogy is the metabolic metaphor that informs materials flow analysis (see below) by analogizing firms, regions, industries, or economies with the metabolism of an organism (Ayres and Simonis, 1994; Fischer-Kowalski, 1998; Fischer-Kowalski and Hüttler, 1998). Whether or not there is a significant difference between the ecological and metabolic metaphors is a matter of friendly dispute. For one view, see Erkman (1997).

Systems Perspective

Industrial ecology emphasizes the critical need for a systems perspective in environmental analysis and decision making. The goal is to avoid narrow, partial analyses that can overlook important variables and, more importantly, lead to unintended consequences. The systems orientation is manifested in several different forms:

- use of a life cycle perspective,
- use of materials and energy flow analysis,

Figure 1 Typology of ecosystems.

- use of systems modeling, and
- sympathy for multidisciplinary and interdisciplinary research and analysis.

The effort to use a life cycle perspective, that is, to examine the environmental impacts of products, processes, facilities, or services from resource extraction through manufacture to consumption and finally to waste management, is reflected both in the use of formal methods such as life cycle assessment (LCA) and in attention to approaches that imply this cradle-to-grave perspective and apply it in managerial and policy settings as well as in research contexts. This latter group includes product chain analysis (Wisberg and Clift, 1999), integrated product policy (IPP, also known as product-oriented environmental policy) (Jackson, 1999), greening of the supply chain (Sarkis, 1995), and extended producer responsibility (EPR) (Lifset, 1993).

Analysis of industrial or societal metabolism, that is, the tracking of materials and energy flows on a variety of scales is also motivated by a system orientation. Here reliance of research in industrial ecology on mass balances – making sure that inputs and outputs of processes add up in conformance with the first law of thermodynamics – reflects an effort at comprehensiveness. Because of the use of mass balances on these different scales, industrial ecology often involves the mathematics of budgets and cycles, and stocks and flows. By tracking chemical usage in a facility (Reiskin et al., 1999), nutrient flows in a city (Björklund et al., 1999), flows of heavy metals in river basins (Stigliani et al., 1994), or bulk materials in national economies (Adriaanse et al., 1997), industrial ecology seeks to avoid overlooking important uses of resources and/or their release to the environment. The tracking of materials and energy is sometimes embedded in the consideration of natural, especially biogeochemical cycles and of how anthropogenic activities have perturbed those flows. For example, the study of anthropogenic perturbations of the nitrogen cycle is an important contribution of industrial ecology (Ayres et al., 1994).

This same effort to examine human–environment interaction from a holistic perspective is manifested in formal systems modeling including dynamic modeling (Ruth and Harrington, 1997), use of process models (Diwekar and Small, 1998), and integrated energy, materials, and emissions models such as MARKAL MATTER (2000) and integrated models of industrial systems and the biosphere (Alcamo et al., 1994). Such systems modeling not only increases the comprehensiveness of environmental analysis; it can also capture some of the interactions among the factors that drive the behavior of the system being studied (for example, Isaacs and Gupta, 1997). Conceptual discussions of the nature of industrial ecology and sustainable development have highlighted the importance of nonlinear behavior in human and environmental systems and argued that chaos theory and related approaches hold out potential for the field (Ruth, 1996; Allenby, 1999a), but little such work has been done to date.

Finally, the imperative for systems approaches is also reflected in a sympathy for the use of techniques and insights from multiple disciplines (Lifset, 1998a; Graedel, 2000). There have been some notable successes (Carnahan and Thurston, 1998; van der Voet et al., 2000), but multidisciplinary analysis – where several disciplines participate but not necessarily in an integrative fashion – is difficult and interdisciplinary analysis – where the participating disciplines interact and shape each other's approaches and results – is even more so. Interdisciplinarity remains an important challenge for not only industrial ecology, but all fields.

Technological Change

Technological change is another key theme in industrial ecology. It is a conspicuous path for pursuing the achievement of environmental goals as well as an object of study (Ausubel and Langford, 1997; Grübler, 1998; Norberg-Bohm, 2000; Chertow, 2001). In simple, if crude, terms, many in the field look to technological innovation as a central means of solving environmental problems. It should be noted, however, that while that impulse is shared widely within the field, agreement as to the degree to which this kind of innovation will be sufficient to solve technological problems remains a lively matter of debate (Ausubel, 1996; Graedel, 2000).

Ecodesign (or design for environment – DFE) is a conspicuous element of industrial ecology. By incorporating environmental considerations into product and process design *ex ante*, industrial ecologists seek to avoid environmental impacts and/or minimize the cost of doing so. This is technological innovation at the microlevel, reflecting technological optimism and the strong involvement of academic and professional engineers. Ecodesign frequently has a product orientation, focusing on the reduction in the use of hazardous substances, minimization of energy consumption, or facilitation of end-of-life management through recycling and reuse. Implicitly, ecodesign relies on the life cycle perspective described earlier by taking a cradle-to-grave approach. Increasingly, it also strives for a systems approach, not only by considering impacts throughout the product life cycle, but also by employing comprehensive measures of environmental impact (Keoleian and Menerey, 1994).

Ecodesign is complemented by research that examines when and how technological innovation for environmental purposes is most successful in the market (Preston, 1997; Chertow, forthcoming). The focus on technological change in this field also has a macro version, examining whether technological change is good for the environment or how much change (of a beneficial sort) must be accomplished in order to maintain environmental quality. Here the IPAT equation (*I*mpact *P*opulation × *A*ffluence × *T*echnology) has provided an analytical basis for parsing the relative contributions of population, economic growth (or, viewed in another way, consumption) and technology on environmental quality (Wernick et al., 1997b; Lifset, 2000; Chertow, 2001). The equation provides a substantive basis for discussion of questions of carrying capacity implicit in the definition of industrial ecology offered earlier.

Role of Companies

Business plays a special role in industrial ecology in two respects. Because of the potential for environmental improvement that is seen to lie largely with technological innovation, businesses as a locus of technological expertise are an important agent for accomplishing environmental goals. Further,

some in the industrial ecology community view command-and-control regulation as importantly inefficient and, at times, as counterproductive. Perhaps more significantly, and in keeping with the systems focus of the field, industrial ecology is seen by many as a means to escape from the reductionist basis of historic command-and-control schemes (Ehrenfeld, 2000a). Regardless of the premise, a heightened role for business is an active topic of investigation in industrial ecology and a necessary component of a shift to a less antagonistic, more cooperative and, what is hoped, a more effective approach to environmental policy (Schmidheiny, 1992).

This impulse to view business as a 'policy-maker rather than a policy-taker' (Socolow, 1994, p. 12) is reflected in a diverse set of analyses and initiatives that explore the efficacy of beyond-compliance environmental strategies and behavior. These include product take back (Davis, 1997), microeconomic rationales for beyond-compliance behavior (Reinhardt, 1999), corporate environmental innovation pursued to maintain autonomy (Sharfman et al., 1998), corporate strategy and sustainable development (Hart and Milstein, 1999), and macro-level analyses of the effectiveness of voluntary policy schemes (Harrison, 1998).

Dematerialization and Eco-Efficiency

Moving from a type I to a type II or III ecosystem entails not only closing loops, but using fewer resources to accomplish tasks at all levels of society. Reducing resource consumption and environmental releases thus translates into a cluster of related concepts: dematerialization, materials intensity of use, decarbonization, and eco-efficiency. Dematerialization refers to the reduction in the quantity of materials used to accomplish a task; it offers the possibility of decoupling resource use and environmental impact from economic growth. Dematerialization is usually measured in terms of mass of materials per unit of economic activity or per capita and typically assessed at the level of industrial sectors, regional, national, or global economies (Wernick et al., 1997a; Adriaanse et al., 1997). Decarbonization asks the analogous question about the carbon content of fuels (Nakicenovic, 1997). Inquiry in this arena ranges from analysis of whether such reductions are occurring (Cleveland and Ruth, 1998), whether dematerialization per se (that is, reduction in mass alone) is sufficient to achieve environmental goals (Reijnders, 1997) and what strategies would be most effective in bringing about such outcomes (Weizsacker et al., 1997). The intersection between investigation of dematerialization on the one hand, and other elements of industrial ecology such as industrial metabolism with its reliance on the analysis of the flows of materials on the other is clear. There is also overlap with industrial ecology's focus on technological innovation. This is because investigations of dematerialization often lead to questions about whether, at the macro- or sectoral level, market activity and technological change autonomously bring about dematerialization (Cleveland and Ruth, 1998) and whether dematerialization, expressed in terms of the IPAT equation, is sufficient to meet environmental goals.

At the firm level, an analogous question is increasingly posed as a matter of ecoefficiency, asking how companies might produce a given level of output with reduced use of environmental resources (Fussler, 1996; OECD, 1998; DeSimone et al., 1997). Here, too, the central concern is expressed in the form of a ratio: output divided by environmental resources (or environmental impact). The connection between this question and industrial ecology's focus on the role of the firm and the opportunities provided through technological innovation is conspicuous as well.

Forward-Looking Analysis

One final element of this field is worth noting. Much of research and practice in industrial ecology is intentionally prospective in its orientation. It asks how things might be done differently to avoid the creation of environmental problems in the first place, avoiding irreversible harms and damages that are expensive to remedy. Ecodesign thus plays a key role in its emphasis on anticipating and designing out environmental harms. More subtly, the field is optimistic about the potential of such anticipatory analysis through increased attention to system-level effects, the opportunities arising from technological innovation and from mindfulness of need to plan and analyze in and of itself. This does not mean that history is ignored. Industrial metabolism, for example, pays attention to historical stocks of materials and pollutants and the role that they can play in generating fluxes in the environment (Ayres and Rod, 1986). However, industrial ecology does not emphasize remediation as a central topic in the manner of much of conventional environmental engineering.

Putting the Elements Together

There are (at least) two ways in which these themes and frameworks can be integrated into a larger whole. One is to view industrial ecology as operating at a variety of levels (**Figure 2**): at the firm or unit process level, at the interfirm, district, or sector level and finally at the regional, national, or global level. While the firm and unit process are important, much of industrial ecology focuses at the interfirm and interfacility level, in part, as described above, because a systems perspective emphasizes unexpected outcomes – and possibly environmental gains – to be revealed when a broader scope is used and because pollution prevention, a related endeavor, has already effectively addressed many of the important issues at the firm, facility, or unit process level.

Another way to tie the elements together is to see them, as in **Figure 3**, as reflecting the conceptual or theoretical aspects of industrial ecology, on the one hand, and the more concrete, application-oriented tools and activities on the other. In this framework, many of the conceptual and interdisciplinary aspects of the field comprise the left side of the figure, while the more practical and applied aspects appear on the right side.

The Goals of Industrial Ecology

Given this overview of the elements of industrial ecology, it is possible to entertain more complicated questions about this field. One set of especially notable and knotty questions revolve around the goals of industrial ecology. Clearly, the field is driven by concerns about human impact on the biophysical environment. Put simplistically, the goal is to improve and

Figure 2 The elements of industrial ecology seen as operating at different levels.

maintain environmental quality. Just as clearly, such a statement of goals does not begin to speak to the multiple dimensions of the research or practice in this field.

Reducing Risk versus Optimizing Resource Use

Industrial ecology emphasizes the optimization of resource flows where other approaches to environmental science, management, and policy sometimes stress the role of risk. For example, pollution prevention (P2) (also known as cleaner production or CP) emphasizes the reduction of risks, primarily, but not exclusively, from toxic substances at the facility or firm level (Allen, 1996). Underlying this focus is an argument that only when the use of such substances is eliminated or dramatically reduced can the risks to humans and ecosystems be reliably reduced. In contrast, industrial ecology takes a systems view that typically draws the boundary for analysis more broadly – around groups of firms, regions, sectors, and so on – and asks how resource use might be optimized, where resource use includes both materials and energy (as inputs) *and* ecosystems and biogeochemical cycles that provide crucial services to humanity (Ayres, 1992). In concrete terms, this means industrial ecology will sometimes look to recycling where P2 will emphasize prevention (Oldenburg and Geiser, 1997). The differences between industrial ecology and P2 are not irreconcilable either conceptually or practically (van Berkel et al., 1997). In conceptual terms, P2 can be seen as a firm-level approach that falls under the broader rubric of industrial ecology (as shown in **Figure 2**). In concrete terms, the difference in actual practices by operating entities may not be great, although careful empirical work documenting how these two frameworks have differed in shaping decision making has not

Figure 3 Industrial ecology conceptualized in terms of its system-oriented and application-oriented elements.

been conducted. However, some interesting analysis has been conducted of the risks posed by the recycling of hazardous materials, asking whether it is indeed possible to recycle such substances in an environmentally acceptable manner (Socolow and Thomas, 1997; Karlsson, 1999).

This is not the only way in which industrial ecology differs from allied fields in its orientation toward risk. The focus of industrial ecology on the flows of anthropogenic materials and energy is not often carried further than the point of release of pollutants into the environment. In contrast, much of traditional environmental science focuses precisely on the stages that follow such release – assessing the transport, fate, and impact on human and nonhuman receptors. Similarly, risk assessment and environmental economics focus on the damages to humans and ecosystems, only sometimes looking upstream to the source of pollutants and the human activities that generate them. In this respect, industrial ecology can be seen as providing a complementary emphasis to these fields by concentrating on detailed and nuanced characterization of the sources of pollution. In a related vein, research in industrial ecology often examines perturbations to natural systems, especially biogeochemical cycles, arising from anthropogenic activities. The impacts of such perturbations can be construed in terms of risks to human health and economic well-being as well as to ecosystems, but the analysis of perturbations differs from the manner in which risk assessment – typically focused on threats to human health – is often conducted. This is not to suggest that industrial ecology ignores questions of risk, fate and transport or environmental endpoints. The intense work on methodologies for life cycle impact assessment (Udo de Haes, 1996) is but one example of the field's efforts to systematically incorporate questions of environmental impact. Further, there is work in the field that integrates fate and transport into such analyses (Potting et al., 1998; Scheringer et al., 1999).

Another aspect of the focus on flows and releases rather than damages and endpoints is that the threats posed by releases – especially of persistent pollutants – endure and the receptors can change in a manner that later causes harms that may not be captured in a typical risk assessment. For example, cadmium deposition to agricultural soils that takes place as a result of naturally occurring cadmium contamination of phosphate fertilizers may not cause significant human health or ecological damage as long as fields are limed and thereby kept alkaline. If the fields are taken out of production, liming is likely to end. Soil pH will thereby increase, and cadmium may become biologically available and environmentally damaging (Stigliani and Anderberg, 1994: Chapter 40).

Positive and Normative Analysis

One apparent tension related to the goals of industrial ecology relates to whether the field is positive (descriptive) or normative (prescriptive). If it is positive, then industrial ecology seeks to describe and characterize human–environment interactions, but not necessarily to alter them. On the other hand, if industrial ecology is normative, then some degree of human or environmental betterment is intrinsic to the goals of the field. This tension is reflected in multiple meanings accorded to key terms in the field. For example, the phrase 'industrial ecosystem' refers to facilities or industries that interact in a biophysical sense. Often it is a label for industrial districts like Kalundborg, where residuals are exchanged among colocated businesses. Leaving aside an especially loose usage that denotes any group of facilities, firms, or industries, the question arises as to whether an industrial ecosystem necessarily refers to a desirable arrangement – where, for example, the participating firms extensively exchange residuals and thereby minimize releases of pollutants into the environment – or to a neutral description of a network of firms, which might constitute either good industrial ecosystems (with considerable closing of loops and little pollution) or bad industrial ecosystems (with linear flows of resources and large amounts of pollution)[2]. The point is not the ambiguity in the terminology, but the difference in the emphasis that it reflects. Are there desirable end states that are integral to the notion of industrial ecology? Can one be an 'industrial ecologist' if one does not think that, more often than not, the closing of materials loops brings about environmental improvement? Is it necessary to think that the environmental situation is quite severe to engage in research in or the application of industrial ecology?

The ambiguity, in general, of the boundary between positive and normative endeavors plays a role here. Clearly, some fields exist at one pole or the other. Physics seeks to describe the physical universe without reference to ethical or other prescriptive principles. Theology, on the other hand, is obviously concerned with what ought to be. Economics, like many social sciences, represents a complex middle ground. On the one hand, it conceives of itself as value neutral and engaged in the study of markets and the allocation of scarce resources. Yet, on the other, the field frequently offers advice of the sort 'if the goal is x, then the appropriate choice is y.' In this conception, the assertion of the value or importance of 'x' originates from outside the discipline, maintaining the apparent value neutrality of the analysis. But economists typically argue that the goal should be maximization of utility (at the individual level) and of social welfare (at the societal level) in a manner that sharply constrains what 'x' might be and carrying with it an implicit set of value choices. Further, the analysis that economics uses to deduce y from x is argued by many to be value laden (see, for example, Frank et al., 1993).

Yet this tension may be overstated. Contemporary engineering sciences fuse the positive and the normative without destroying the distinctiveness of each (Ehrenfeld, 2000a). In practice, most industrial ecologists appear to enter the field out of concern for the potential environmental implications of production and consumption and the opportunities for improvement. It is thus regarded by most practitioners – those operating on the right side of **Figure 3** – as a normative endeavor, one that is informed by the positive analysis generated by the activities on the left side of the figure. This characterization does not resolve all disputes about the normative status of field (Allenby, 1999b; Boons and Roome, 2000), but it does, we think, narrow the purview of the disagreements to questions about whether the field has teleological (i.e., goal-oriented) characteristics (Ehrenfeld, 1997, 2000b) and to matters of meta-analysis such as by whom and, by what criteria, these sorts of debates are decided (Boons and Roome, 2000).

Transformative and Incremental Change

Once some degree of normative content in the field is acknowledged, it is easy to entertain a related question of goals: is the environmental improvement that is sought large, transformative, and discontinuous or is it incremental and continuous with current practice and infrastructure? Much of the conceptual discussion in industrial ecology looks to transformative change through the development and/or implementation of radically innovative technology, changes in consumption patterns, or new organizational arrangements. This type of transformative change can range from shifts to a hydrogen (Marchetti, 1989) or carbohydrate economy (Morris and Ahmed, 1992), factor 4 or factor 10 reductions in materials throughput (Weizsacker et al., 1997), a shift to the use of services in lieu of products (Stahel, 1994; Mont, 2000) or new political–economic structures. At the same time, much of the practical work in ecodesign and life cycle management aims at more modest changes in product design protocols, materials choice, interfirm relationships, or environmental policy. Still other analyses assert that current arrangements meet the test of industrial ecology, employing the practices characteristic of the field, and need no significant improvement (Linden, 1994). Yet the tension between transformative and incremental change may be overdrawn to the extent that, in many circumstances, the two paths are not mutually exclusive: the more modest changes can be pursued while the more ambitious ones are debated, refined, and implemented. To the extent that such tensions do exist, they frequently reflect differing assessments of the severity of the current environmental situation as well as ideological differences about the degree to which market economies and current political institutions can and do achieve environmental goals.

The Boundaries of Industrial Ecology

Like the question of goals, the boundaries of the field are subject to varying interpretations. They cannot be defined deductively from first principles; there is no authoritative epistemology in industrial ecology. At the same time, views on what are part of or outside this field shape, what is published in the *Journal of Industrial Ecology*, what is included in compendia such as this handbook and what projects receive funding from sources focusing on the development of industrial ecology.

One of the considerations with respect to the boundaries is whether industrial ecology should address not only 'what' but 'how' (Andrews, 2000). Investigations of 'what' inform our understanding of the character of technological and natural systems – characterizing the manner in which these systems behave and interact, and under what circumstances environmental situations that humans deem preferable (for example, the absence of ozone holes in the atmosphere) might occur, much as in the definition of industrial ecology quoted in the beginning of this article. In that respect, the 'what' investigations include the what-if questions described above with respect to the normative aspects of industrial ecology: 'What if different materials were used for packaging; would carbon dioxide emissions decrease and global warming slow?' Some industrial ecologists, however, argue that the field must also embrace social, political, and economic questions of 'how.' That is, given the identification of a preferred outcome, what strategies should be employed to bring about that outcome (Andrews, 2000; Jackson and Clift, 1998).

Thus the 'how' questions are largely a province of the social sciences. Sociology, economics, anthropology, psychology, political science, and related fields have the potential to help identify strategies that are more likely to succeed. Nonetheless, the social sciences are not confined to 'how' questions (Fischhoff and Small, 1999). They can also indicate what is happening as when, for example, social scientists investigate the quantity and character of consumption in households and how it drives production and waste management activities and therefore environmental outcomes (Duchin, 1998; Noorman and Schoot Uiterkamp, 1998).

Most industrial ecologists would agree that such knowledge is crucial, but some would argue that that knowledge should remain lodged in allied fields, otherwise the boundaries and identity of industrial ecology will become so expansive as to be diffuse. Further complicating this tension are questions of whether these different sorts of inquiry can be construed as modular. That is, can they be pursued independently and *subsequently* melded to generate reliable insights? Or does their intellectual and organizational separation inevitably mean that the modular inquiries will be impoverished, incapable of integration, or even fundamentally misleading (Lifset, 1998b)? Put more simply, *must* the questions that industrial ecology seeks to answer be pursued on an interdisciplinary basis to produce reliable answers? Ultimately, it will be the productivity of the various approaches in generating conceptual insights and practical knowledge that will determine their adoption[3].

Conclusion

As a new field, industrial ecology is a cluster of concepts, tools, metaphors, and exemplary applications and objectives. Some aspects of the field have well-defined relationships, whereas other elements are only loosely grouped together, connected as much by the enthusiasm of the proponents as by a well-articulated intellectual architecture. We do not see this looseness as a fatal flaw in an emerging field, but rather as an opportunity for creativity and constructive discourse, and as a challenge.

Notes

1. We put 'natural' in quotation marks because there are many ways in which the notion of natural ecosystems is complicated or contested. Many analysts argue that there are no longer any ecosystems unaffected by humankind, although clearly, even in this view, there is wide variation in the degree to which human activity dominates nonhuman ecosystems.

More subtly, the notion of 'natural' is socially constructed and subject to varying interpretations across cultures (Williams, 1980; Cronon, 1996).

2. Multiple meanings extend to other terms in the field. 'Industrial ecology' is variously used to mean (1) a field of study, (2) a set of environmentally desirable practices, and (3) the same practices as in meaning (2), but viewed neutrally. Such plurality of meanings is not unusual, however: 'history' refers both to past events and to the discipline that systematically studies those events.
3. Disagreement about industrial ecology's boundaries is exacerbated by more pedestrian conflation of the ethics and values, the social sciences, and public policy analysis. In particular, nonsocial scientists sometimes do not realize that the social sciences have a primarily positive/analytical focus, characterizing how humans behave, whereas it is the humanities that investigate and debate matters of values. Public policy analysis is often instrumental, asking how effectively certain strategies accomplish a set of public goals. Few industrial ecologists would suggest that the field offers powerful tools for adjudicating disputes over values, even if those disputes are important to the field.

Addendum

1. Addendum to the Lifset and Graedel article, "Industrial Ecology: Goals and Definitions" for *International Encyclopedia of Social and Behavioral Sciences*.
2. In the 15 years since this chapter was written, industrial ecology has evolved from an emerging to a rapidly growing field. Methodologies have matured, concepts have evolved, and empirical understanding has grown substantially.
3. Industrial symbiosis, the sharing and exchange of resources by geographically proximate facilities, has moved from an academic curiosity to an important component of environmental policy in countries such as China, Korea, and the United Kingdom. Research has shifted from identification and characterization of individual instances of industrial symbiosis to theorizing (Chertow, 2007) and hypothesis testing and statistical analysis (Paquin et al., 2014).
4. The concept of a 'Type III' industrial ecology in which resources are reused indefinitely (as described in the chapter) originated in the 1990s as a vision of a sustainable future. It gathered considerable force in 2006 when it was included in China's 11th five-year plan under the rubric of the 'circular economy'(Yuan et al., 2006). The focus of the circular economy concept, which has considerable popular appeal (Ellen MacArthur Foundation, 2012), has gradually shifted from the 3Rs (reduce, reuse, recycle) to a broader approach that encompasses upstream (supply chain) considerations, cleaner production, eco-industrial parks, and a number of other practices.
5. Despite the attractiveness of the circular economy concept, it has been pointed out that circularity has its limits (Kral et al., 2013). Basic thermodynamics, dissipative uses such as fertilizer and paint, and human frailties all conspire against a perfectly circular economy. Allwood (2014) argues for an analytically grounded and technologically sophisticated approach – efforts in product life extension, lightweight design, and component reuse. The combination of the circular economy vision with engineering innovations holds out the possibility of more effectively optimizing the use of materials.
6. Quantification of resource flows – circular or otherwise – has remained an important foundation for industrial ecology. In a little more than a decade, industrial ecologists used material flow analysis (MFA) to quantify the cycles of many of the elements, and to do so at both country and global levels (Chen and Graedel, 2012). As a result, production, flows into use, recycling, loss, and often trade flows as well, are now much better understood than was formerly the case. MFA has also been extended to incorporate material stocks, generating insights such as the possibility that anthropogenic stocks may saturate on a per capita basis in developed countries (Müller et al., 2006). Economy-wide MFA, in which large categories of material use are quantified in bulk, has been institutionalized (Eurostat, 2014) and used, for example, to quantify material footprints of nations to challenge the notion that the use of natural resources has been decoupled from economic growth (Wiedmann et al., 2013) and to generate theories regarding large-scale socioecological transition (Fischer-Kowalski and Haberl, 2007).
7. Input–output analysis (IOA) has become a key tool in industrial ecology, providing a means of assessing economy-wide environmental impacts. IOA is also frequently used in 'footprinting' (quantitative tracing of the impact of human activity through the economy and then into the biophysical environment) of carbon, water, biocapacity, and other resources (Lifset, 2014).
8. Material flow and stock analysis are increasingly conceptualized as metabolic processes, extending industrial ecology's use of the biological analogy. Research on the metabolism of cities has blossomed (Kennedy et al., 2007), assisting cities in their efforts to quantify and manage their carbon emissions. Urban carbon footprinting has revealed the crucial role – and ambiguity – in assigning responsibility for carbon emissions from infrastructure and trade beyond the urban boundary (Ramaswami et al., 2012).
9. The manufacture of products for international trade, and the role of consumption in driving resource flows and emissions, has become a central focus of industrial ecology in multiple domains. Lin et al. (2014), for example, have used trade statistics and air pollution models to demonstrate that 17–36% of air pollutants emitted in China relate directly to exports, with a noticeable shift in air quality from consuming countries to producing countries. Motivated by the dramatic increase in attention to climate change in the past decade and a half, carbon accounting and carbon footprinting have emerged as a means of quantifying the global warming impacts of the production and consumption of specific products and activities at various scales. At the national and international level, carbon footprinting and multiregional input–output analysis have allowed researchers to quantify greenhouse

gas (GHG) emissions associated with the final consumption of goods and services, e.g., for 73 nations and 14 aggregate world regions (Hertwich and Peters, 2009). By assessing GHG emissions according to a region's consumption rather than activities within its territorial boundaries, this approach provided an influential, alternative perspective on the drivers of global warming.

10. As global populations grow and as richer mineral deposits are depleted over time, concerns have arisen as to the long-term availability of mineral resources in sufficient quantities (Nakamura and Sato, 2011). The subjects for such discussions have ranged from phosphorus, essential for food production (Cordell et al., 2009), to gold, widely employed in investment, jewelry, and technology (Kerr, 2012). An industrial ecology approach to this issue has been to quantify specific resources in ore deposits, to compile production, demand, and recycling statistics, and to compare that information with anticipated demand (Northey et al., 2014). Substantial effort has also gone into assessing 'criticality' by determining supply risk and vulnerability to supply disruption for a number of elements (Nassar et al., 2012). The result of this research has been to embed industrial ecology firmly in discussions of the human life style and of sustainability.
11. Among the most high-profile developments in industrial ecology has been the widespread adoption of life cycle thinking as a form of systems-oriented environmental analysis, and the associated tool, LCA. Use of LCA to assess products, services, and technologies by business, government, and academe to identify environmental 'hotspots' and to support environmental decision-making has become common globally. LCA, for example, is the basis for regulation of the global warming emissions from transportation fuels in California (the Low Carbon Fuel Standard) and the source of considerable debate about the indirect impacts of biofuels production on land use in agriculture (Searchinger et al., 2008).
12. LCA has undergone significant methodological development including the incorporation of input–output analysis (Hendrickson et al., 2006). Distinctions have emerged between attributional LCA which provides a snapshot of potential environmental impacts and consequential LCA which seeks to model the consequences of a decision or change in the phenomenon being studied. Efforts are growing to incorporate social impacts into LCA under the rubric of 'social LCA' (Norris, 2012), part of a broader trend to incorporate social science in many of the subfields within industrial ecology.
13. The maturing of industrial ecology is reflected not only in the research output sketched above, but also in its role in the fifth Assessment of the Intergovernmental Panel on Climate Change (IPCC, 2014), where industrial ecologists played central roles in the working group on industry (WG3) among others. Studies such as those mentioned above demonstrate the transition of industrial ecology from basic conceptualizing and exploratory analysis to substantiated and increasingly theoretically embedded generalization and sophisticated model development.

Industrial Geography

Abstract

From early craft production methods to the rise of the knowledge economy, spatial dynamics have shaped the organizational structure of industry. However, the global industrial landscape has been created not only by the location decisions of firms but also by historical processes related to technological change, social interaction, and cultural influences. Current industrial geography reflects the manifestation and evolution of these processes through successive eras.

Industrial geography is the study of the global industrial landscape, which serves as the background context for studies of industrial location. Industrial geography is "not simply the summation of individual location; it is the consequence of historical processes that transcend the ability (and often the perception) of any individual firm" (Harrington and Warf, 1995: p. 115). Industrial geography represents the accretion of material reality and human ingenuity, which are in turn shaped by the dominant mode of wealth creation. The geographic approach to understanding industrial structures emphasizes how the organizational structure of industry manifests across space and interacts with and helps shape the lived experience of people. As such, the industrial geography of today is the sum of past practices, technology eras, and social relationships.

Industrial geography is related to but distinct from industrial location. Industrial location is the study of the location decision-making processes of firms and reflects the trade-off between access to natural resources and access to markets. Early work in this field focused on the fixed-location competitive firm (Weber, 1971). Subsequent work incorporated concerns including the nature of the market (Lösch, 1954), the economic spillover effects of firms in the same location (Hoover, 1948), and the importance of and variability in pools of labor (Storper and Walker, 1989). In contrast to the study of industrial location, this article focuses on the historical development of the industrial landscape.

The Industrial Geographic Landscape

What most people see today in the industrial landscape is the sum of multiple periods of economic development. In the American and Western European settings, the old mill town is a physical representation of a type of industrial landscape that evolved prior to or in conjunction with the industrial revolution. By beginning from the late eighteenth and early nineteenth centuries, a considerable period of the economic history that forms the bedrock of the contemporary industrial landscape is left out. Under feudalism, for example, industrial activity was focused on the manor and the creation of goods for local consumption. Occasional surpluses were produced that were traded in market towns (Rosenberg and Birdzell, 1986). With the decline of feudalism and the ascendancy of urban centers of trade and production, the industrial landscape began to emerge in the form of urban workshops. Independent manufacturers were only one source of manufactured goods, however. Merchants were key to early industrialization; they organized not only the markets for manufactured goods, but also production outside the influence of urban guilds. The 'putting out' system of rural manufacturing extended the influence of the industrial landscape significantly beyond urban centers. Rural manufacturing provided a check on urban wages but eventually declined when merchants could no longer guarantee or control output from rural manufacturers.

Prior to the industrial revolution, the production of manufactured goods unfolded within a system of handicraft manufacture under the purview of a master craftsman. One or more journeymen or apprentices assisted an exceedingly clever and dexterous person, the master.

The regulation of this form of production rested with guilds, production organizations that regulated skills and access to skills, and to a much lesser extent access to markets (Landes, 1969). By restricting access to skills, craftsmen were able to preserve their markets and ensure public belief in the credibility of their products. Guilds acted as brakes on the expansion of output and thus overproduction. In later periods, guilds also thwarted technological change, a detail that led ultimately to their own demise.

The movement from craft production to the putting out system was an outgrowth of the merchants' increasing control over producers. The expansion of the market and the lack of access to and knowledge of its extensiveness placed artisans at a decided disadvantage. Market reach and knowledge of the tastes and preferences of distant customers was a clear advantage of merchants who could accumulate demand and periodically fill it (Glasmeier, 1990).

Putting out, while highly efficient in an era with few economic alternatives, grew less and less viable as an organizing system over time. As workers grew wealthier and additional avenues of income creation became available to them, merchants had increasing difficulty controlling the output and quality of cottage industry goods. During periods of market growth, meeting new demand became harder as workers began to assert more control over their lives and labor process. The need to find an alternative, more controllable system of manufacture became overwhelming as markets grew and demand burgeoned. In Britain, geographic range had essentially been reached and in some cases exceeded. Transport costs became a real impediment.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72026-5

As control of workers' efforts lessened, and the limits of geographic expansion were reached, a slow but steady transformation took place as machines began to replace human labor, and the organization of labor within specific locales and structures provided the control employers sought. The movement to a factory-based system of manufacture was neither rapid nor complete. The slow demise of the putting out system provides one explanation for the emergence of factories: the need to control labor and the production process. Volumes have been written on this subject, from a wide variety of perspectives and with an equally broad range of emphases. What is important here is the way the movement from a more decentralized to a more centralized system removed control of production from workers laboring in the manufacture of a good, and turned it over to the capitalist. Of additional importance is the recognition that the process of change did not occur in the same way simultaneously in all relevant locations.

The ways in which mechanization unfolded across industrial sectors are also relevant to understanding industrial geography. The reasons for early and rapid mechanization in some sectors and for resistance of machine support in others can be reduced to several intervening factors. The nature of the good largely determined its susceptibility to mechanization. This attribute went hand in hand with the extent of the market for the good. If the good was a high-value/low-volume one and of a luxurious nature, labor costs were relatively insignificant and thus there was a minimal stimulus to change, unless of course the transition to machines was twinned with a movement toward a broader market and a more widely disseminated good. In this case, market shifts could simply require change in order to hold a longer term market position. Institutional factors could also serve as impediments to change. The number of possible explanations supporting the lack of investment is certainly sufficient to see that the prospect of a smooth functioning factor market acting as a stimulus for change was inherently contingent on elements other than just the short-term costs of production.

Early centers of industrialization were highly specialized – a result of natural resource location as well as of built-up competencies (e.g., in the local labor force) – the initial impetus of which was often accidental. Trade was essential to the growth of industrialization in place. The formation of institutions and social relationships combined with key developments in technology facilitated and ultimately encouraged trade among regions. Fundamental to the success of trade across long distances was the development of shipping technology that allowed the movement of large volumes of goods in reasonable time. Simultaneously, in order for trade to occur, mechanisms were needed to reduce risk and to finance the time between the manufacture and the sale of a good. With the creation of a number of institutional innovations such as the banking, credit, and insurance sectors, industrialization in the late eighteenth and early nineteenth centuries moved beyond local production for local consumption and toward production for trade.

The industrial revolution marks a critical moment in the formation of the industrial landscape. Essential to the pervasive diffusion of the industrial revolution was the ability to harness power sources in order to concentrate economic activities in space. Simultaneously, the development of new technologies led both to an enhanced capacity to organize industrial activity and to the creation of new manufactured goods themselves. Finally, the organization of production within factories allowed the achievement of economies of scale and task specialization across the production process.

Before the beginning of the eighteenth century, the primary source of power used in production was human and animal (Rosenberg and Birdzell, 1986). This dependence significantly restricted the size, scale, and location of industrial activity. With the ability to harness inanimate power sources, industrial activity moved toward a larger scale and a greater degree of specialization. First water, then charcoal, and finally coal became the defining power sources of the early industrial revolution. The industrial landscape began to spread out as manufacturing became unshackled from water power sources. Timber and charcoal were an intermediate solution; both, however, quickly declined in importance when most of the trees were cut down and charcoal became uneconomic to manufacture. With the discovery of large supplies of coal, production spread further and moved quickly beyond a relatively few industrial centers.

Technological change is a critical marker of the evolving industrial landscape. In addition to the ability to utilize inanimate energy sources, a hallmark of the industrial revolution was the development of machines that replaced human action. Metal cutting and metal shaping machines were vital to the formation of the industrial equipment industry. New materials and the understanding of the chemical basis of new materials made possible more complex manufacturing processes and new products. This in turn led to specific spatial concentrations of firms in the same industry, as divisions of labor formed and fanned out in independent enterprises.

The Organization of Industry in the Factory Era

The organization of capitalist enterprises into factories occurred as both merchants and manufacturers sought to control and coordinate an entire production process. During the craft era, workers exhibited some control over the labor process (declining through time). Capital's increasing span of control had important implications for the volume of output and therefore the size of markets that could be served, the level and source of innovations, and the sources and control of power. The need to harness these capabilities into a more centralized system of command and control had major implications for how industrial systems evolved. According to Lazonick (1991: p. 25), "The transition to the era of proprietary capitalism brought the integration of asset ownership with managerial control and with it an internalization of aspects of the craft system, in particular, in order for firms to generate (what were by the standards of the time) high-quality products at low unit costs." Further, "firms relied on an ample supply of highly skilled and well-disciplined labor. Senior workers—who eventually came to be known collectively as the aristocracy of labor—not only provided their own skills to the building and operating of machinery, but also recruited junior workers whom they trained and supervised on the shop floor."

The heavy reliance on skilled labor had obvious spatial implications. Firms were more or less bound to a particular

place. This dependence on labor is one of the prime determinants of spatially bound production systems, aptly captured by such well-known observers as Marshall (1997). The external economies within such a complex were substantial. Materials, labor, and services (distribution) were sufficiently honed that spatial proximity enabled work in progress to flow through its vertically specialized branches and to market its output (Lazonick, 1991: p. 26). These regional concentrations facilitated high levels of specialization. Consequently, employers' ongoing reliance on skilled labor to organize work on the shop floor diminished the need for business firms to invest in the development of managerial structure and organizational capabilities (Lazonick, 1991: p. 26). It also meant that pressures to cut costs were resolved through market transactions rather than through internal restructuring.

The system was self-perpetuating. Because proprietors had access to this complementary system of transactions, it was unnecessary to invest in or develop complex managerial structures. Instead, in the early phases of factory industrialization, proprietors tended to own single establishments and rely on the market for the provision of necessary inputs. Firms mostly remained small, and new establishments were formed to fill niches. The manufacturing process was inherently labor intensive and reliant on a cadre of skilled and unskilled workers to manipulate the raw material into final, finished form. The advantages of this supply system, combined with the benefits of a labor force that was self-reproducing, resulted in low fixed costs. Although problems of coordination would eventually become disabling, Britain, and other countries including Switzerland, built a globally competitive industry in the early nineteenth century based on just such a system of organization.

What unseated this remarkably flexible system was the emergence of mass production and the manufacture of volumes of products, all of more or less the same quality and capability. In the early era of mass production, the American system became the model to emulate. Unfolding in fits and starts, this system has been characterized as "the sequential series of operations carried out on successive special-purpose machines that produce interchangeable parts" (Hounshell, 1984: p. 15). Implicit in this description was the move away from a dependence on skilled labor and from a system based around fragmented and decentralized production producing highly variable, relatively high-cost goods (Hounshell, 1984). Costs had not been the only concern. Equally important were similarity of parts, interchangeability, and rapid production.

The Emergence of Managerial Capitalism and Factories

The transition to machine-based, vertically integrated, large-scale industrial manufacturing occurred over a long period of time. There are examples of metal cutting machines assisting in the rough shaping of parts for final finishing as early as the middle of the eighteenth century. However, it was the middle of the nineteenth century before widespread implementation of this technological and organizational innovation occurred. The movement toward this form of production was neither pervasive nor persistent. There were many obstacles to overcome, not least the construction of the necessary machinery and the resolution of the inherent conflicts presented by machine-based output to established labor relations and hence to the production system itself (Lazonick, 1991). Ultimately, the movement toward the American system caused turmoil throughout the entire system as machine-made parts and large-scale assembly yielded an unprecedented volume of goods. Many problems were associated with the flow of goods, and spilled over into the acquisition of consistent inputs and, equally important, the development of an effective means of distribution. Goods were no longer produced with a proximate market in mind. Indeed, the international supply of foreign markets became an increasingly important part of firm strategy. To produce at large scale necessarily meant distribution at large scale, ushering in the move toward managerial capitalism.

The evolution toward machine-based manufacturing and the ensuing complementary innovations in scale and scope of production, distribution, and management of the modern industrial enterprise arose rather gradually, starting in the 1870s (Chandler, 1991). The rise of the multiunit, capital-intensive corporation was the result of three investments. First, production levels had to be large enough to utilize economies of scale and scope of new technological innovations. Second, marketing and distribution capabilities had to be of a scale large enough to sell the goods produced by the new processes of production in the volume in which they were made. Third, a managerial hierarchy was needed to manage and coordinate the operations of large-scale production and distribution and to allocate resources for future production and distribution (Chandler, 1991: p. 432). That this new paradigm first took hold primarily in the United States and Germany has much to do with the relatively late industrialization of the two countries compared with Britain, and hence the absence of a preexisting labor process and managerial system to overcome. In the United States, the shortage of skilled labor placed a premium on developing machine-based alternatives to industrial production. Preceding the American Civil War and strongly afterward, American firms in a wide range of industries pursued mechanical solutions to the expansion of production to achieve economies of scale and serve burgeoning domestic and international markets.

The rise of the managerial corporation brought with it the integration of multiple functions, multiple units, multiple products, and all the attendant physical and human resources. Although each unit had independent capabilities to execute and manage the enterprise, coordination was offered and accomplished by middle managers who were themselves managed by top officials of the corporation. Quite strikingly, the emergence of this mode of organization and coordination arose rather quickly at the end of the nineteenth and the beginning of the twentieth centuries and was most observed in a subset of all industries comprising the US economy. These industries tended to be concentrated in certain industrial sectors, to consist of firms that were vertically integrated within the same industry group, and to be characterized by high-volume, capital-intensive production processes. In other words, what linked these firms were product characteristics that yielded the need for a uniform managerial structure designed to confront and control problems of production and distribution while benefiting from the potential associated with specific sectoral characteristics.

The sectors and firms most successful in executing the full complement of attributes of the modern corporation were those that benefited from the scale and scope linked to standardization of the production process. At the same time, however, there were other prerequisites to effective implementation, particularly relating to market control. To support the huge capital costs required to achieve economies of scale, a relatively few players had to exercise market power. The emergence of oligopolies in such sectors as oil, steel, and heavy machinery went hand in hand with the rise of the modern corporation. Control was both seized and achieved through investments in up- and downstream linkages, a capability that most smaller, more consumer-oriented goods producers could not make.

With the emergence of the managerial corporation, firms were now in a position to own and control resources and markets distributed across space. The spatial organization of the national economy evolved from production for local consumption, to regional markets of production and consumption, and finally to national markets and corporate structures of spatially decentralized production systems. The ability to standardize products and to produce at mass scale, twinned with the development of national brands and brand recognition, resulted in huge corporations that controlled vast business assets.

The Rise of Collective Capitalism

The model of market coordination embodied in managerial capitalism remained an effective organizing system until the 1960s. The lack of cutthroat international competition, and the presence therefore of stable markets, buoyant growth, and rising standards of living, provided hospitable conditions for the cultivation and persistence of the large, vertically integrated corporation. The seeds of turmoil that would come to destabilize this system of production, consumption, and market regulation were sown much earlier in the century, however, and laid dormant until after World War II. The challenge to this dominant system arose, ironically, as a new competitor – in this case Japan – coupled long-standing and underappreciated competency in the production of goods with state-supported (yet private-sector-led) manufacture of new products capable of competing directly in the world's most sophisticated industries and its most developed markets (Conroy, 1995). The national pursuit of both import substitution and export-led development policies provided infant industries with the protection required to achieve economies of scale and hence low overall costs. Accustomed to developing technological competency through technology transfer, the Japanese successfully adopted and adapted major innovations, primarily from the United States, to take the lead in key consumer and producer products over the postwar period.
